Release History 12
1 Introduction 13
1.1 Overview 14
1.2 Module Allocation and Instances within Device Domains 14
1.3 Functional Block Diagram 15
1.4 Device MAIN Domain 17
1.4.1 Arm® Cortex®-A53 Subsystem (A53SS) 17
1.4.2 Arm Cortex-R5F Processor (R5FSS) 17
1.4.3 Deep Learning Accelerator (C7x256v) 18
1.4.4 Vision Pre-processing Accelerator 19
1.4.5 Depth and Motion Perception Accelerator 19
1.4.6 Mailbox (MAILBOX) 20
1.4.7 Spinlock (SPINLOCK) 20
1.4.8 DDR 32-bit Subsystem (DDR32) 20
1.4.9 Data Movement Subsystem (DMSS) 20
1.4.10 General Purpose Input/Output Interface (GPIO) 21
1.4.11 Inter-Integrated Circuit Interface (I2C) 21
1.4.12 Serial Peripheral Interface (SPI) 21
1.4.13 Universal Asynchronous Receiver/Transmitter (UART) 21
1.4.14 3-port Gigabit Ethernet Switch (CPSW3G) 22
1.4.15 Universal Serial Bus (USB) Subsystem 2.0 22
1.4.16 Universal Serial Bus 3.1 Subsystem (USBSS) 22
1.4.17 Serializer/Deserializer (SERDES) 23
1.4.18 Peripheral Component Interconnect Express Subsystem (PCIE) 23
1.4.19 Enhanced Pulse-Width Modulation Module (EPWM) 23
1.4.20 Enhanced Quadrature Encoder Pulse Module (EQEP) 24
1.4.21 Enhanced Capture Module (ECAP) 24
1.4.22 Controller Area Network (MCAN) 24
1.4.23 Flash Subsystem (FSS) with Octal Serial Peripheral Interface (OSPI) 24
1.4.24 General Purpose Memory Controller (GPMC) 25
1.4.25 Error Location Module (ELM) 25
1.4.26 Multi-Media Card/Secure Digital Interface (MMCSD) 25
1.4.27 Memory Cyclic Redundancy Check 26
1.4.28 Windowed Watchdog Timer/Real Time Interrupt 26
1.4.29 TIMER 26
1.4.30 Audio Tracking Logic 26
1.4.31 Camera Subsystem 26
1.4.32 Dual Clock Comparator 27
1.4.33 Error Signaling Module (ESM) 27
1.4.34 Multi-Channel Audio Serial Port (McASP) 27
1.4.35 Camera Streaming Interface Receiver (CSI-RX) 28
1.4.36 Display Subsystem (DSS) 29
1.4.37 Open LVDS Display Interface transmitter (OLDI-TX) 29

About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for the device, visit the Texas Instruments website at www.ti.com.

Glossary

TI Glossary	This glossary lists and explains terms, acronyms, and definitions.

Support Resources

TI E2E™ support forums are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

Export Control Notice

Recipient agrees to not knowingly export or re-export, directly or indirectly, any product or technical data (as defined by the U.S., EU, and other Export Administration Regulations) including software, or any controlled product restricted by other applicable national regulations, received from disclosing party under nondisclosure obligations (if any), or any direct product of such technology, to any destination to which such export or re-export is restricted or prohibited by U.S. or other applicable laws, without obtaining prior authorization from U.S. Department of Commerce and other competent Government authorities to the extent required by those laws.

Chapter 1
Introduction

This chapter introduces the features, subsystems, and architecture of the J722S Processor Platform high-performance System-on-Chip (SoC).

Note

This document describes the Superset architecture, processors and peripherals of the J722S Family of SoCs, which are part of the K3 Multicore SoC architecture platform. Not all features are available on each family of devices. The superset J722S devices are available for preproduction software development. Software should constrain the features used to match the intended production device. For more information on the specific features, processors and peripherals available on a particular device, refer to the Device Comparison table in the corresponding device-specific Data sheet.

The J722S Processor Platforms are hereinafter commonly referred to as J722S*platform*, *device*, or *SoC*.

TI limits support for this family of SoCs to features that are supported via Software Development Kits (SDK). The SDK “build sheet” is available for download as part of each SDK and should be referenced to understand the subset of SoC hardware functionality that is available in software.

This document describes the Superset features of the Modules integrated into this Device. See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

1.1 Overview

1.2 Module Allocation and Instances within Device Domains

Module Full Name	Module Abbreviation	Device Domain		
		MCU	MAIN	WKUP
Quad-Core Arm Cortex A53 Subsystem	A53SS	-	1	-
Single-Core Arm Cortex-R5F Subsystem	R5FSS	1	1	1
Deep Learning Accelerator (C7™ DSP 256b + MMA)	DLA	-	2	-
Vision Pre-processing Accelerator	VPAC	-	1	-
Depth and Motion Perception Accelerator	DMPAC	-	1	-
Interprocessor Communication - Mailbox	Mailbox	-	1	-
Interprocessor Communication - Spinlock	Spinlock	-	1	-
Dual Data Rate Random Access Memory (32-Bit) Subsystem	DDRSS	-	1	-
Data Movement Subsystem	DMSS	-	2	-
Peripheral DMA	PDMA	-	3	-
General Purpose Input/Output	GPIO	1	2	-
Inter-Integrated Circuit	I2C	1	5	1
Multi-channel Serial Peripheral Interface	MCSPI	2	3	-
Universal Asynchronous Receiver/Transmitter	UART	1	7	1
3 Port Gigabit Ethernet Switch	CPSW	-	1	-
Universal Serial Bus 2.0	USB2	-	2	-
Universal Serial Bus 3.0	USB3	-	1	-
Peripheral Component Interconnect Express	PCIe	-	1	-
Serializer/Deserializer	SERDES	-	2	-
Enhanced Pulse Width Modulation Module	EPWM	-	3	-
Enhanced Quadrature Encoder Pulse Module	EQEP	-	3	-
Enhanced Capture Module	ECAP	-	3	-
Controller Area Network Interface	MCAN	2	2	-
Audio Tracking Logic	ATL	-	1	-
Flash Memory Subsystem	FSS	-	1	-
Octal Serial Peripheral Interface	OSPI	-	1	-
General Purpose Memory Controller	GPMC	-	1	-
Error Location Module	ELM	-	1	-
Multi-Media Card/Secure Digital Interface	MMCSD	-	3	-
Global Time Counter	GTC	-	-	1
Real Time Interrupt/Windowed WatchDog Timer	RTI/WWDT	1	5	1
Dual-Mode Timer	TIMER	4	8	2
Dual Clock Comparator	DCC	2	9	-
Error Signaling Module	ESM	-	1	1
Memory Cyclic Redundancy Check Controller	MCRC	1	1	-
Multi-channel Audio Serial Port	McASP	-	5	-
Camera Serial Interface Receiver	CSI-RX	-	4	-
Camera Serial Interface Transmitter	CSI-TX	-	1	-
Display Subsystem	DSS	-	2	-
Video Encoder/Decoder Engine	CODEC	-	1	-
DPHY Receiver	DPHY4RX		4	-

1.4 Device MAIN Domain

This section describes the modules integrated in the device MAIN domain.

1.4.1 Arm® Cortex®-A53 Subsystem (A53SS)

The integrated 64-bit Arm® Cortex®-A53 subsystem (A53SS) supports the following main features:

- Full Arm®v8-A architecture compliancy
- Advanced Single Instruction Multiple Data (SIMD) and floating point extension (Arm® Neon™)
- Floating-Point Unit (FPU) VFPv4
- Armv8 Cryptography Extensions
- Arm General Interrupt Controller (GICv3) architecture
- In-order pipeline with symmetric dual-issue of most instructions
- 32KB program and 32KB data Level 1 (L1) Cache
- Support for up to four timers within each Cortex-A53 core
- Arm® CoreSight™ Debug and Trace Architecture
- ECC protection for L1 data cache and L2 Cache
- Parity protection for L1 Instruction Cache
- 128-bit wide, synchronous or asynchronous VBUSM initiator interface
- Dedicated RTI windowed watchdog timer per core
- Support for Big-Endian (BE) and Little-Endian (LE) at core level
- Interface with Arm GIC-500 Interrupt Controller (SoC level, not part of A53SS)
- Advanced power management for low power optimization

1.4.2 Arm Cortex-R5F Processor (R5FSS)

The ARM Core Cortex-R5F processor subsystem (R5FSS) supports the following main features:

- Armv7-R architecture
- R5FSS Memory System
  - 32KB Instruction Cache
    - 4x ways
    - SECDED ECC protected per 64 bits
  - Data Cache
    - 4x ways
    - SECDED ECC protected per 32 bits
  - 64KB tightly-coupled memory (TCM) per CPU
    - SECDED ECC protected per 32 bits
    - TCM hard error cache Implemented in CPU
    - Readable/writable from system
    - 32KB TCMA (ATCM)
    - 16KB TCMB0 (B0TCM)
    - 16KB TCMB1 (B1TCM)
- Full-precision Floating Point (VFPv3)
- 16-region Memory Protection Unit (MPU)
- 8 breakpoints, 8 watch points
- CoreSight Debug Access Port (DAP)
- CoreSight ETM-R5 interface (CTI, ETM)
- Performance Monitoring Unit (PMU)
- 32-bit to 36-bit Region-based Address Translation (RAT) on memory access initiators
- Integrated Vectored Interrupt Manager (VIM) per core with 256 Interrupt Inputs each
  - Programmable interrupt priority (4-bit)
  - Programmable interrupt enable mask
  - Software-generated interrupts

Copyright © 2026 Texas Instruments Incorporated

– Synchronous clock domain crossing on all core interfaces

Note

CORE0 has 64KB of TCM.

Note

These details describe a superset of the R5FSS memory configuration. For additional details on device memory availability, please refer to the device-specific Datasheet.

1.4.3 Deep Learning Accelerator (C7x256v)

- Single Core C7x/MMA subsystem
  - C7x ISA and RISC-V G ISA extensions
    - Vector DSP, 40 GFLOPS
    - 256-bit vector width
    - Deep-learning Matrix Multiply Accelerator (MMA), up to 2 TOPS
  - L1 memory architecture
    - 32KB I-cache
    - 64KB D-cache
  - L2 memory architecture
    - Repurposing of its L2/EL2 embedded memory for use by SOC resources when C7x/MMA/DRU are disabled
    - 1.25MB L2 with ECC protection on L2 SRAM
    - Unified Memory Controller (UMC) facilitates L2 SRAM accesses from CPU and SOC (DMAs) as well as EMIF accesses from CPU.
    - DRU (DMA engine) integrated that facilitates data transfer between L2, VPAC and EMIF.
      - Data compression support
      - Event bus interface integrates with SOC DMSS
      - Tightly coupled with C7x/MMA (DRU is not available for use when the C7x/MMA is disabled)
  - Interrupts
    - Local event controller (CLEC) integrated within CorePac for routing and handling of DRU interrupts, CPU generated IPC events to SOC, interrupts coming from SOC
  - Security
    - Support for C7x Authenticated Boot. Security is in-context during boot to facilitate the authentication and loading of the C7x image.
    - The C7x L2 SRAM (UMC) should not be used for storing security content as there is no protection of UMC memory from C7x itself. In a threat scenario, the C7x can be activated if in reset to execute malicious code to access data in UMC thereby defeating a protection for security data in UMC.
    - No security should be inferred from DRU as this IP is out of scope for security.
    - TrustZone debug controls (DBGEN, NIDEN, SPIDEN, SPNIDEN) are supported
  - Safety
    - Support for reporting safety errors to SOC via interrupt
  - Debug
    - Independent debug interface supporting access to embedded features
    - Debug features include: Core debug, Advanced Event Triggering, Trace, CTSETs, and an embedded CP Tracer Aggregator with bus probes on internal memory interfaces
  - Power Management
    - support for granular gated clock domains to support low power modes and to support memory interface utilization while IP disabled.
  - Advanced SOC Integration
    - Dedicated PLL for full flexibility in performance and power trade-offs
    - Dedicated windowed watchdog timer per core

1.4.4 Vision Pre-processing Accelerator

The Vision Pre-processing Accelerator (VPAC) provides a set of common vision primitive functions, performing various pixel data processing tasks, such as: color processing and enhancement, noise filtering, wide dynamic range (WDR) processing, lens distortion correction, pixel remap for de-warping, on-the-fly scale generation, on-the-fly pyramid generation, and offloads these common tasks from the main SoC processors (ARM, DSP, and so forth). The VPAC includes the following processing and infrastructure sub-modules:

- Vision Imaging Sub-System (VISS) which provides raw data image processing such as:
  - Wide Dynamic Range (WDR) merge
  - Defect Pixel Correction (DPC)
  - Lens Shading Correction (LSC)
  - Global/Local Brightness and Contrast Enhancement (GLBCE)
  - Advanced Spatial Noise Filter (NSF4V)
  - Edge Enhancement (EE)
  - Demosaicing
  - Color conversion
- Lens Distortion Correction (LDC) block, which provides data reading from memory (DDR or on-chip) and applies perspective transformation as well as correction of lens distortion (including fisheye lenses).
- Multi-Scalar (MSC) block reads data from memory (DDR or on-chip) to internal shared level 2 (SL2) memory and generates up to 10 scaled outputs from one or two inputs, with various scaling ratios.
- Noise Filter (NF) block reads data from memory (DDR or on-chip) to internal SL2 memory and does Bilateral filtering to remove noise.
- Hardware Thread Scheduler (HTS) provides inter-processor communication among various VPAC sub-modules (VISS, LDC, MSC and NF) as well as with the local DMA Engine (UTC).
- Internal Shared Level 2 (SL2) memory for data exchange across VPAC sub-modules (VISS, LDC, MSC and NF) and from DDR/MSMC, using the K3 Data Movement Architecture (DMA) mechanism
- Load/Store Engine (LSE) which performs data load and store tasks on a the SL2 memory for the hardware accelerator algorithm cores
- VISS to LDC direct OTF (On-the-Fly) for multi-camera
- YUV422 10 and 12 bit format support on all units except NF (for example, LDC/MSC)
- Simultaneous visual (HV) and analytics (MV) output to system memory including L3 flex connect, saving need for additional read from system memory for HV+MV processing.
- Chromatic Aberration Correction (CAC) to support lower cost lens
- RGBIR support

1.4.5 Depth and Motion Perception Accelerator

The Depth and Motion Perception Accelerator (DMPAC) computes dense stereo depth maps (*depth*) and dense optical flow vectors (*motion*) from camera inputs. The stereo and optical flow processing is partitioned into two top level sub-blocks: the Dense Optical Flow (DOF) engine and the Stereo Disparity Engine (SDE). The DOF and SDE blocks share a common local memory, DMA, external messaging and control infrastructure. The DMPAC provides the following main features, among others:

- Image resolution up to 2MPix (maximum horizontal resolution up to 2048 pixels; maximum vertical resolution up to 1024 pixels)
- Maximum throughput up to 183MPix/sec for DOF, and up to 82MPix/sec for SDE
- Simultaneous operation of Stereo (1MPix@30fps) and Optical flow (1MP@30fps)
- 12-bit fully packed luminance data input pixel data format (other formats supported through conversion)
- Packed 16-bit (disparity) or 32-bit (flow vector) output data formats
- Shared Level 2 (SL2) memory sub-system, which serves the data transfer of the DOF and SDE blocks
- Unified Transfer Controller (UTC), which serves as a DMA engine
- Hardware Thread Scheduler (HTS) block for messaging and control mechanism
- Counter, Timer and System Event Trace (CTSET) module, which provides event tracing capability for the Stereo and Optical Flow hardware threads

Copyright © 2026 Texas Instruments Incorporated

1.4.6 Mailbox (MAILBOX)

Integrated in MAIN domain: One Mailbox (MAILBOX) module to facilitate the communication between the various on-chip processor cores of the device by providing a queued mailbox-interrupt mechanism with the following main features:

- 1x clusters
- 32-bit message width
- Message reception and queue-not-full notification using interrupts
- Non-intrusive emulation

1.4.7 Spinlock (SPINLOCK)

One Spinlock module with (256 hardware semaphores) for synchronizing the processes running on multiple cores in the device.

1.4.8 DDR 32-bit Subsystem (DDR32)

Integrated in MAIN domain: One instance of DDR 32-bit Subsystem (DDR32) (also referred to as DDRSS) is used as an interface to external SDRAM devices which can be utilized for storing program or data. The DDRSS provides the following main features:

- Support of LPDDR4 memory type (up to 4000 MT/s)
- 32-bit memory bus interface with in-line ECC
- Up to 8 GB memory address range
- Support of dual rank configuration
- Support of automatic idle power saving mode when no or low activity is detected
- Class of Service (CoS) - three latency classes supported
- Dynamic change of refresh reach via SW for extended temperatures
- Prioritized refresh scheduling
- Statistical counters for performance management

1.4.9 Data Movement Subsystem (DMSS)

Integrated in the MAIN domain: One Data Movement Subsystem (DMSS) can be used for efficient transfer of data support between software, firmware, and hardware in all combinations. It consists of the following main modules:

- Packet DMA Controller
- Block Copy DMA Controller
- Ring Accelerator provides hardware acceleration to enable straightforward passing of work between a producer and a consumer and has the following main features:
  - Supports independent memory-mapped ring structures
  - Supports various modes for each ring based on usage and compatibility
  - Provides single-word deep shared incoming Transfer Response FIFO
  - Provides bit-wide source VBUSM read/write target interface for accesses from DMA controller entities
- Secure proxy module is a modified version of the proxy module and in addition has the following main features:
  - Provides proxy function to store large data bursts that a host can only access in smaller amounts
  - Supports a configurable number of threads, where each has their own independent proxy function
  - Keeps the large data burst coherent until the complete data has been accessed
  - Allows for interleaved access between multiple hosts or tasks using multiple proxy threads
  - Supports a configurable target resource. The target has a configurable number of channels, size of each channel and base address
  - Supports a programmable fixed queue for each proxy thread
  - Supports multiple producers all writing to the same queue
  - Supports programmable thresholds for when to generate events
  - Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce

Copyright © 2026 Texas Instruments Incorporated

  - Optionally supports dynamic clock gating
- Interrupt Aggregator modules provide a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. Main features are as follows:
  - 64-bit VBUSP target using 64-bit registers
  - Provide a set of TI Interrupt Architecture compliant interrupt status and mask registers which are used to pass specific event status to one or more host blocks.
  - Provides an optional set of Unmapped event (UNMAP) which can take an 'unmapped' event from the ingress ETL and generate a Global event on the egress Event Transport Lane (ETL) interface.
  - Provides an optional set of Global Event Input (GEVI) counters which can count events delivered via an ingress Event Transport Lane (ETL)
  - Provides an optional set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL
  - Provides an optional set of Global Event Input (GEVI) 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on two egress ETL interfaces

1.4.10 General Purpose Input/Output Interface (GPIO)

Integrated in MAIN domain: General Purpose Input/Output (GPIO) module that provide dedicated general-purpose pins that can be configured as either inputs or outputs. The GPIO module main features include:

- Support of 9 banks x 16 GPIO pins
- Support of up to 9 banks of interrupt capable GPIOs
- Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO pin
- Set/clear functionality per individual GPIO pin

1.4.11 Inter-Integrated Circuit Interface (I2C)

Integrated in MAIN domain: Five instances of the multi-controller Inter-Integrated Circuit (I2C) interface module, each with the following main features:

- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- 8-bit-wide data access
- Support of multi-controller transmitter/peripheral receiver and receiver/peripheral transmitter modes
- Built-in FIFOs with fixed size of 32 bytes.

1.4.12 Serial Peripheral Interface (SPI)

Integrated in MAIN domain: Three instances of the Serial Peripheral Interface (SPI) module with the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to channels in controller mode, or single channel in receiver mode
- Support for various controller multichannel modes
- Single interrupt line for multiple interrupt source events
- Support of start-bit write command
- Support of start-bit pause and break sequence
- Built-in FIFO available for a single channel

1.4.13 Universal Asynchronous Receiver/Transmitter (UART)

Seven Instances of the configurable Universal Asynchronous Receiver/Transmitter (UART) interface module have the following main features:

- 16C750-compatible interface
- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation

Copyright © 2026 Texas Instruments Incorporated

- Programmable sleep mode
- Baud-rate from 300 bits/s up to 3.6864 Mbits/s with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

Note

Only one UART instance has support for support full modem control functions. All other UART instances will support only the TX, RX, RTS, and CTS signals.

1.4.14 3-port Gigabit Ethernet Switch (CPSW3G)

Integrated in MAIN domain: One instance of the 3-port Gigabit Ethernet Switch (CPSW3G) subsystem provides Ethernet packet communication for the device. The CPSW3G subsystem provides the following main features:

- Two external Ethernet ports with selectable RGMII and RMII interfaces and one internal Communications Port Programming Interface (CPPI) port.
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Support of eight priority level Quality Of Service (QOS) - 802.1p
- Support for Audio/Video Bridging (P802.1Qav/D6.0 and 802.1Qaz)
- Ethernet port reset isolation
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
- Differentiated Services Code Point (DSCP) Priority Mapping (IPv4 and IPv6)
- IPV4/IPV6 UDP/TCP checksum offload
- Priority Based Flow Control (801.1QBB) and Flow Control (802.3x) Support
- Wire rate switching (802.1d)
- Store and Forward Switching
- Non-Blocking switch fabric
- Support of Time Sensitive Network - IEEE P902.3br/D2.0 Interspersing Express Traffic and IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE) with 512 ALE table entries
- EtherStats and 802.3 Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Maximum frame size of 2020 bytes
- Management Data Input/Output (MDIO) module for PHY Management
- Host port CPPI Streaming Packet Interface
- Emulation support

1.4.15 Universal Serial Bus (USB) Subsystem 2.0

Instantiated in MAIN domain: Two instances of the Universal Serial Bus (USB) subsystem with integrated USB2.0 PHY module has the following main features:

- Dual-Role Device (DRD) capability
- Support of Peripheral (aka Device) mode at High Speed (HS at 480 Mbps) and Full Speed (FS at 12 Mbps)
- Support of Host mode at High Speed (HS at 480 Mbps), Full Speed (FS at 12 Mbps), and Low Speed (LS at 1.5 Mbps)
- Support of Host Negotiation Protocol (HNP)
- Support of USB3 low power protocol states (U1, U2, and U3)
- USB instance contains a single xHCI compliant with xHCI 1.0 specification with internal DMA controller
- Embedded USB 2.0 PHY

1.4.16 Universal Serial Bus 3.1 Subsystem (USBSS)

Instantiated in MAIN domain: One instance of the Universal Serial Bus 3.1 subsystem (USBSS) with integrated USB2.0 PHY module has the following main features:

- Dual-Role Device (DRD) capability

Copyright © 2026 Texas Instruments Incorporated

- Compliant to the USB 3.1 Gen1 Specification
- Supports Peripheral/Device mode at High-Speed (HS at 480 Mbps), and Full-Speed (FS at 12 Mbps)
- Supports Host mode at Super-Speed (SS at 5 Gbps), High-Speed (HS at 480 Mbps), Full-Speed (FS at 12 Mbps), and Low-Speed (LS at 1.5 Mbps)
- Supports Host Negotiation Protocol (HNP)
- Supports USB3 low power protocol states (U1, U2, and U3)
- Single xHCI instance compliant to the xHCI 1.0 specification with internal DMA controller
- ECC on internal RAMs
- Embedded USB 2.0 PHY

1.4.17 Serializer/Deserializer (SERDES)

Integrated in MAIN domain: Two high-speed differential interfaces implemented with the Serializer/Deserializer (SERDES) Multi-protocol Multi-link module with the following main blocks:

- Quad lane PHY with common module for peripheral and Tx clocking handling
- PIPE Rev 4.2 Interface
- Physical coding sub-block for data translation from/to the parallel interface, as well as data encoding/decoding and symbol alignment
- MUX module for device interfaces multiplexing into a single SERDES lane (Tx and Rx)
- A wrapper for sending control and reporting status signals from the SerDes and muxes

1.4.18 Peripheral Component Interconnect Express Subsystem (PCIE)

Integrated in MAIN domain: One instance of the Peripheral Component Interconnect express (PCIe) subsystem module with shared SerDes lines, provides the following main features:

- Compliant to PCI-Express® Base Specification, Revision 4.0 (Version 0.7)
- 1-lane configuration with up to 8.0 Gbps/lane (Gen3).
- Gen3 (8 Gbps 128/130-bit encoding), Gen2 (5 Gbps 8/10-bit encoding), and Gen1 (2.5 Gbps 8/10-bit encoding) with auto-negotiation
- Dual mode: Root Port (RP) or End Point (EP) operation modes, selectable via bootstrap pins
- Dynamic PIPE width change when switching between Gen1/2/3 modes
- Constant 32-bit PIPE width for Gen1/2/3 modes
- Maximum payload size of 128 bytes
- Maximum remote read request size of 4KB
- Dual mode: Root Port (RP) or End Point (EP) operation modes
- Maximum number of non-posted outstanding transactions: 32
- Resizable Base Address Registers (BAR) capability
- Separate Reference Clock with Independent Spread (SRIS)
- Legacy, MSI and MSI-X Interrupt Support
- 32 outbound address translation regions
- Precision time measurement (PTM)

1.4.19 Enhanced Pulse-Width Modulation Module (EPWM)

Integrated in MAIN domain: Three Enhanced Pulse-Width Modulation (EPWM) modules, each with the following main features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two independent PWM outputs that can be used in different configurations (with single-edge operation, with dual-edge symmetric operation or one independent PWM output with dual-edge asymmetric operation)
- Asynchronous override control of PWM signals during fault conditions
- Programmable phase-control support for lag or lead operation relative to other EPWM modules
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both latched and un-latched fault conditions
- Events enabling to trigger both CPU interrupts and start of ADC conversions

Copyright © 2026 Texas Instruments Incorporated

1.4.20 Enhanced Quadrature Encoder Pulse Module (EQEP)

Integrated in MAIN domain: Three 32-bit Enhanced Quadrature Encoder Pulse (EQEP) modules for position, speed, and frequency measurements support, each with the following main features:

- Input synchronization
- Three stage/six stage digital noise filter
- Quadrature decoder unit
- Position counter and control unit for position measurement
- Quadrature edge capture unit for low speed measurement
- Unit time base for speed/frequency measurement
- Watchdog timer for detecting stalls

1.4.21 Enhanced Capture Module (ECAP)

Integrated in MAIN domain: Three Enhanced Capture (ECAP) modules provide accurate timing for different events. When not being used for event capture, its resources can be used to generate a single channel of asymmetrical PWM waveforms (configurable as either one capture input, or as one auxiliary PWM output). Each ECAP module supports the following main features:

- 32-bit time base counter
- 4 x 32 bits event time-stamp capture registers
- 4 stage sequencer (Mod4 counter), synchronized to external events
- Independent edge polarity selection for up to four sequenced time-stamp capture events
- Input capture signal pre-scaling (from 1 to 16)
- Interrupt capabilities on any of the four capture events
- Support of different capture modes (single shot capture, continuous mode capture, absolute timestamp capture or delta mode time-stamp capture)

1.4.22 Controller Area Network (MCAN)

Integrated in the domain: One Controller Area Network interfaces (MCAN) supporting both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications and having the following main features:

- Conforms with CAN Protocol version 2.0 part A, B and ISO 11898-1:2015
- Full CAN FD (up to 64 data bytes) support
- SAE J1939 support
- AUTOSAR support
- Up to 32 dedicated transmit buffers and 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit event FIFO, up to 32 elements
- Up to 128 filter elements
- Maskable interrupts, two interrupt lines
- Timestamp Counter

1.4.23 Flash Subsystem (FSS) with Octal Serial Peripheral Interface (OSPI)

Integrated in MAIN domain: One instance of the Flash Subsystem (FSS) module provides access to external flash devices via Octal Serial Peripheral Interface (OSPI) along with encryption/decryption and in-line ECC protection. FSS supports the following main features:

- Provides one OSPI flash interfaces
- OSPI interface supports:
  - Execute in place (XIP) operation
  - 32-byte Block Copy (BC) operation
  - ECC
- OSPI supports up to 4 devices
- OSPI supports single, dual, quad, or octal SPI devices

Copyright © 2026 Texas Instruments Incorporated

- The OSPI interface has independent power management for low power operations

1.4.24 General Purpose Memory Controller (GPMC)

One instance of the General-Purpose Memory Controller (GPMC) module. The GPMC is dedicated to interfacing with external memory devices and has the following main features:

- Support of 8- or 16-bit-wide data path to external memory devices
- Supports up to 4 independent chip-select regions of programmable size and programmable base addresses on 16MB, 32MB, 64MB, or 128MB boundary in a total address space of
- Support of the following wide range of external memories/devices:
  - Asynchronous or synchronous 8-bit wide memory or device (non-burst device)
  - Asynchronous or synchronous 16-bit wide memory or device
  - 16-bit non-multiplexed NOR flash device
  - 16-bit address and data multiplexed NOR flash device
  - 8-bit and 16-bit NAND flash device
  - 16-bit pseudo-SRAM (pSRAM) device
- Supports various interface protocols when communicating with external memory or external devices:
  - Asynchronous read/write access
  - Asynchronous read page access (4, 8, and 16 Word16)
  - Synchronous read/write access
  - Synchronous read burst access without wrap capability (4, 8, and 16 Word16)
  - Synchronous read burst access with wrap capability (4, 8, and 16 Word16)
- Supports up to 16-bit on-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)

1.4.25 Error Location Module (ELM)

One instance of the Error Location Module (ELM). The ELM module works in conjunction with the GPMC and has the following main features:

- ECC calculations (up to 16-bit) for NAND support and ability to work in both page-based and continuous modes
  - 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
  - Eight simultaneous processing contexts
  - Page-based and continuous modes
  - Interrupt generation on error-location process completion

1.4.26 Multi-Media Card/Secure Digital Interface (MMCSD)

Integrated in MAIN domain: Three Multi-Media Card/Secure Digital (MMCSD) controller modules with the following main features:

- One controller with 8-bit wide data bus
- Two with 4-bit wide data bus
- Support of eMMC5.1 Host Specification (JESD84-B51)
- Support of SD Host Controller Standard Specification - SDIO 3.00
- Integrated DMA controller supporting SD Advanced DMA - ADMA2 and ADMA3
- eMMC Electrical Standard 5.1 (JESD84-B51)
- Multi-Media card features:
  - Backward compatible with earlier eMMC standards
  - Legacy MMC SDR: 3.3/1.8 V, 8/4/1-bit bus width, 0-25 MHz, 25/12.5/3.125 MB/s
  - High Speed SDR: 3.3/1.8 V, 8/4/1-bit bus width, 0-50 MHz, 50/25/6.25 MB/s
  - High Speed DDR: 3.3/1.8 V, 8/4-bit bus width, 0-50 MHz, 100/50 MB/s
  - HS200 SDR: 1.8 V, 0-200 MHz, 8/4-bit bus width, 200/100 MB/s
- SD card support: SDIO, SDR12, SDR25, SDR50, SDR104, DDR50

Copyright © 2026 Texas Instruments Incorporated

1.4.27 Memory Cyclic Redundancy Check

- Memory Cyclic Redundancy Check module used to perform CRC to verify the integrity of a memory system. The MCRC module has the following main feature:
  - Four Channels of CRC Compression based Signature Generation
  - 8, 16, 32, or 64-bit Data Size
  - Maximum Length PSA based on 64-bit Polynomial
  - Programmable 20 bit pattern counter per channel
  - Three Operating Modes: Auto, Semi-CPU, Full CPU
  - MCRC or CPU can perform signature verification for each Channel
  - Timeout Interrupt if CRC is not performed within the time limit

1.4.28 Windowed Watchdog Timer/Real Time Interrupt

- Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module providing timer functionality for operation systems and benchmarking code with the following main features:
  - Two independent 64 bit counter blocks
  - Four configurable compare registers for generating operating system ticks
  - Free running counter 0 can be incremented by either the internal pre-scale counter or by an external event
  - Selectable RTI clock input (derived from any of the available clock sources)
  - Fast enabling/disabling of events

1.4.29 TIMER

- Dual mode Timer (TIMER) module with support of the following main features:
  - Free running 32-bit upward counter
  - Generates a 1-ms tick with a 32.768-kHz functional clock
  - Interrupts generated on overflow, compare and capture
  - Supported modes of operation: compare and capture, auto-reload and start-stop
  - Programmable divider clock source (2^n, where n = [0-8])
  - Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
  - On-the-fly read/write register (while counting) for systems operation and benchmarking code

1.4.30 Audio Tracking Logic

The Audio Tracking Logic (ATL) module, which is used by HD Radio™ applications to synchronize the digital audio output to the baseband clock, supports the following main features:

- Contains four ATL instances, for HD Radio support and asynchronous sample rate conversion assistance
- Each instance tracks the time error between two syncs (local Audio Word Select [AWS] and Baseband Word Select [BWS])
- Each instance selects between 8 mux choices for BWS and 8 mux choices for AWS
- Each instance generates modulated ATCLK clock signals with software-initiated pulse stealing
- Selection between interface or functional clock to run error counting timers and to derive modulated clock outputs
- Clock and reset management: receives clock and reset signals from the device PSC module
- Hardware reset
- Local software reset

1.4.31 Camera Subsystem

Camera Subsystem unites three camera streaming interfaces – receiver and transmitter, allowing the device to stream video inputs from multiple cameras to the video processing accelerator (VPAC) or to internal memory and to output CSI-2 protocol image data to any device that supports MIPI CSI-2 protocol. Main modules are as follows:

- Camera Streaming Interface Receiver (CSI_RX_IF) with the following main features:
  - Compliant to MIPI CSI-2 v1.3+ and MIPI CSI-2 v2.0

Copyright © 2026 Texas Instruments Incorporated

  - Supports up to 16 virtual channels per input
  - Supports one 4MP camera or eight 2MP camera streams
  - Supports data rate up to 2.5Gbps per lane (wire rate)
  - Supports 1, 2, 3, or 4 Data Lane connections to MIPI D-PHY Receiver (DPHY_RX)
  - Over 25 different programmable formats including YUV420, YUV422, RGB, Raw, and User Defined
  - Supports four independent (simultaneous) output streams:
    - Two VP 32-bit streams to VISS inputs of VPAC image processing accelerator
    - One (up to 4 channels) PPI 16-bit pixel retransmission interface to Camera Streaming Interface Transmitter (CSI_TX_IF)
    - One (up to 32 Channels) DMA interface through a 128-bit Packet Streaming Interface Link (PSI_L) connection to NAVSS for transfers to memory:
- Functional and data path error interrupts
- ECC support
- MIPI D-PHY Receiver (DPHY_RX) with the following main features:
  - Allows the device to input video streams from external sensor cameras and other CSI2 compliant sources
  - Compliant to MIPI D-PHY standard v1.2
  - Supports up to 4 data and 1 clock lanes
  - Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
  - Clock lane Control / Interface logic type: CIL-SCNN for HS and low power receiving
  - Data lane Control / Interface logic type: CIL-SFAN for HS and low power receiving
  - Data lanes can be independently operated in HS or ULP mode
  - Swapping of DP/DN signals within each clock/data pair
- Camera Streaming Interface Transmitter (CSI_TX_IF) with the following main features:
  - Compliant to MIPI CSI-2 v1.3+, MIPI CSI-2 v2.0, and MIPI D-PHY v1.2
  - Data rate up to 2.5 Gbps per lane (wire rate)
  - Supports 1, 2, 3, or 4 Data Lane connections to MIPI D-PHY Transmitter (DPHY_TX)
  - Over 25 different programmable formats including YUV420, YUV422, RGB, Raw, and User Defined
  - Support of 16 virtual channels
  - Support of four configurable input streams

1.4.32 Dual Clock Comparator

- Dual Clock Comparator (DCC) modules, used to determine the accuracy of a clock signal during the time execution of an application, each having the following main features:
  - Two independent counter blocks count clock pulses from each clock source
  - Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
  - Configurable time base for error signal
  - Error signal generation when one of the clocks is out of spec
  - Clock frequency measurement

1.4.33 Error Signaling Module (ESM)

Error Signaling Module (ESM) for safety-related events and/or errors aggregation from throughout the device into one location supports the following main features:

- Selectable low and high priority interrupt error pin prioritization of each error event
- Up to 1024 level or pulse error event inputs
- Error signal routed out of device through MCU_ ESM error signal
- Configurable time base for error signal
- Error forcing capability
- Internal redundant flops on safety critical fields

1.4.34 Multi-Channel Audio Serial Port (McASP)

The McASP module supports the following features:

Copyright © 2026 Texas Instruments Incorporated

- Transmit control section consisting of:
  - Transmit state machine supporting IIS and DIT modes
  - Transmit formatter supporting IIS and DIT options
  - Transmit clock generation with auto-switch on bad clock detect
  - Transmit frame sync generation
  - Transmit TDM control
- Receive control section consisting of:
  - Receive state machine implementing supported protocols
  - Receive clock generation
  - Receive frame sync generation
  - Receive TDM control
  - Option to synchronize to transmit control section
- Multiple shift registers (2 to 16 specified at module generation):
  - Individual transmit / receive / off selection
  - Transmit in IIS or DIT mode
  - Flexible order in memory to ease DMA operation versus pinout
  - TDM mode function selection (Z, 0, 1)
- Single RX interrupt generation, with individual enables for:
  - Data Ready: all slots, last slot
  - Error: overrun, unexpected frame sync, bad clock
- Two DMA events (RX, TX)
- Slot counter exported with DMA request to enable per-slot DMA request (or left/right, at minimum)
- Automatic mute output pin option with programmable polarity on error detect

1.4.35 Camera Streaming Interface Receiver (CSI-RX)

The CSI_RX module supports the following features:

- Fully Compliant to MIPI CSI v1.3 Specification
- Supports up to 16 virtual channels per input (partial support for MIPI CSI v2.0)
- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to MIPI D-PHY
- Programmable formats including YUV420, YUV422, RGB, Raw, and User Defined (over 25 different formats supported)
- Four Independent (Simultaneous) Output Streams:
  - Two VID32 streams to VISS inputs of VPAC Image Processing Accelerator (2x 16-bit Pixels Per Clock)
  - One (Up to 4 Channel) PPI 16-bit pixel Retransmission interface to CSI-TX (2x 16-bit Pixels Per Clock)
  - One (Up to 32 Channel) DMA interface through a 128 bit PSIL Connection to NavSS/DMSS for transfers to memory.
- TI Wrapper Interrupts:
  - PSIL fifo overflow
  - VP0 frame/line mismatch
  - VP1 frame/line mismatch
- CSI2-RX core functional (informational) interrupts:
  - Stream Abort Process Complete (x4)
  - Stream Stop Process Complete (x4)
  - Reception of Generic Short Packet
  - Reception of Short Packet
  - Reception of Long Packet
  - Deskew Entry
  - ECC Spares Error (protocol non-compliance)
  - D-PHY Sleep
  - D-PHY Wakeup
- For stream 0, stream monitor interrupts:
  - Line Count Error Interrupt

Copyright © 2026 Texas Instruments Incorporated

  - Frame Mismatch Error Interrupt
  - Frame Count Error Interrupt
  - FCC Stop Interrupt
  - FCC Start Interrupt
  - Line/Byte Interrupt
  - Timer / Timer Interrupt
- CSI Core / Datapath Error Interrupts:
  - Stream FIFO Overflow (x4)
  - Invalid Short Packet Received
  - Invalid Access to Configuration Register Space
  - Data ID Error in Packet Header
  - Header ECC Error (Correctable/Uncorrectable)
  - Payload CRC Error
  - Front (D-PHY to CSI-RX) FIFO Overflow

1.4.36 Display Subsystem (DSS)

The Display Subsystem IP module supports the following features:

- Two display outputs (for a single DSS7_UL instance)2
  - Up to 24-bit per pixel parallel or embedded sync output
  - Up to 300MHz pixel clock
  - Support for RGB/YUV422 modes
  - Support for progressive/interlaced modes
- Two input display processing pipelines
  - One video pipeline supporting full RGB and 8/10-bit YUV data formats with 3/5-tap 16-phase scaler capable of 0.25x to 16x resizing.
  - One video_lite pipeline supporting full RGB and 8/10-bit YUV data formats (no resizing support)
- Two Overlay Managers with multi layer alpha blending
- One DMA controller capable of supporting up to 2K input source width.
  - 48bit addressing (256 TB reach)
- On-the-fly X/Y-axis flip of the source (Flip/Mirror mode support)
- Safety check (freeze frame detection and data correctness check)

1.4.37 Open LVDS Display Interface transmitter (OLDI-TX)

The OLDI_TX module integration (two instances) supports OLDI resolution up to:

- 1920x1440@60fps with a 200MHz pixel clock in single link mode (2x independent or duplicate displays)
- 3840x1080@60fps with a 300MHz pixel clock in dual link mode

The OLDI_TX module features include:

- OLDI Mapping
  - 3 or 4 LVDS data channels
  - VESA or JEIDA bit mapping
- Multiple OLDI Link Modes
  - Single Link (Duplicate or non-duplicate mode)
  - Dual Link (odd or even data) – Link Off
- Clock Transmission
- ANSI/TIA/EIA644-A compliant VLVDS signaling

1.4.38 MIPI DPHY Receiver

The DPHY_RX module supports the following features:

- Compliant to MIPI D-PHY standard v1.2
- Supports up to 4 data and 1 clock lanes
- Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane

Copyright © 2026 Texas Instruments Incorporated

- Clock Lane **C**ontrol / **I**nterface **L**ogic type is **CIL-SCNN** for HS and low power receiving:
  1. **(S)** Peripheral
  2. **C**lock
  3. **N**/A forward, **N**/A reverse escape mode features
- Data Lane **C**ontrol / **I**nterface **L**ogic type is **CIL-SFAN** for HS and low power receiving:
  1. **(S)** Peripheral
  2. **F**orward direction only for high speed mode
  3. **A**ll forward direction escape mode features are supported
  4. **N**o reverse direction escape mode features are supported
- Data lanes can be independently operated in HS or ULP mode
- Swapping of DP/DN signals within each clock/data pair (Facilitated by CSI_RX_IF controller)

1.4.39 MIPI DPHY Transmitter

The DPHY_TX0 module supports the following main features:

- Compliance to MIPI D-PHY standard version 1.2.
- Supports up to 4 data lanes and 1 clock lane.
- Supports High Speed up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane.
- Supports Escape mode:
  - Remote triggers
  - LP-DT up to 10 Mbps
  - ULPS mode
- Clock Lane **C**ontrol / **I**nterface **L**ogic type is **CIL-MCNN**: [HS-TX, LP-TX]
  1. **(M)** Controller
  2. **C**lock
  3. **N**/A forward, **N**/A reverse escape mode features.
- Data Lane **C**ontrol / **I**nterface **L**ogic type is **CIL-MFAA**: [HS-TX, LP-TX, LP-RX, LP-CD]
  1. **(M)** Controller
  2. **F**orward direction only for High Speed mode
  3. **A**ll forward direction escape mode features are supported
  4. **A**ll reverse direction escape mode features are supported.
- Data Lanes can be independently operated in HS or ULP mode.
- Includes a CMN block with reference generators / resistor calibration and an integrated PLL.
- Fault detection:
  - Contention detection (for example, when RX and TX sides of same link drive opposite LP levels).
  - Sequence error detection (corruption on lanes).

1.4.40 Graphics Processing Unit

The GPU module supports the following features:

- Base architecture, fully compliant with the following APIs:
  - OpenGL ES 3.2
  - OpenCL 1.2 EP
  - Vulkan 1.2
- Tile-based deferred rendering architecture for 3D graphics workloads, with concurrent processing of multiple tiles
- Support for DRM security
- Support for GPU virtualization
  - Up to 8 virtual GPUs
  - Separate IRQ for each OSID
- Multi-threaded Unified Shading Cluster (USC) engine incorporating pixel shader, vertex shader and GP-GPU (compute shader) functionality
- USC incorporates an ALU architecture with high SIMD efficiency

Copyright © 2026 Texas Instruments Incorporated

- Fully virtualized memory addressing (up to 64 GB address space), supporting unified memory architecture
- Fine-grained task switching, workload balancing and power management
- Advanced DMA driven operation for minimum host CPU interaction
- 256KB System Level Cache (SLC)
- Specialized Texture Cache Unit (TCU)
- Compressed Texture Decoding
- Lossless data compression (PVRGC) - The PowerVR's geometry compression, which is performed in the Geometry Processing phase of the 3D graphics workload.
- Dedicated RISC-V processor for firmware execution
- Separate power island for the firmware processor for low latency power domain transitions
- On-Chip Performance, Power and Statistics Registers.
- Resolution Support
  - Frame buffer max size = 8K × 8K
  - Texture max size = 8K × 8K
- Anti-aliasing
  - Maximum 4× multisampling
- Performance
  - Floating Point Operations (F32) - 64 operations per clock
  - Floating Point Operations (F16) - 128 operations per clock
  - Texture performance - 4 texels per clock (@32 BPP)
  - Pixel performance - 4 pixel(s) per clock (@32 BPP)
  - Geometry Performance - 0.25 triangles per clock
  - Max performance
    - ~50 GFLOPS, 4 GTex/s or 4 GPix/s @ 800MHz

1.4.41 Video Accelerator (CODEC)

CODEC module supports the following features:

- HEVC (H.265) Encode Main profiles @ L5.1 High-tier
- H.264 Encode BaseLine/Main/High Profiles @ L.52
- YUV420/YUV422 format
- 8b bit-depth
- I and P frame encoding
- ¼ -pel precision Mition vector
- Search Range in HEVC (+/- 128H, +/-64V)
- Search Range in H.264(+/- 64J, +/-48V)
- 4K resolution at 60 fps
- 8 channel 1080p40 Encode
- Rotation in multiples of 90 degree & vertical and horizontal Mirroring
- 4K resolution at 60fps for decode for all
- 8-channel 1080p30 decode
- 2 VBUSM initiator interfaces for data traffic (Primary and Secondary)
- 48 bit address width
- 128 bit data width
- ChannelID based on Internal Data Requestor
- Data interface at wrap level is synchronous to SoC CBA clocks
- 1 VBUSP 32-bit target interface to access config registers
- Fuse Controllevel high interrupt
- All memories are non-repair memories

1.5 Device MCU Domain

This section describes the modules integrated in the device MCU domain.

Copyright © 2026 Texas Instruments Incorporated

Note

In TI documentation, the MCU Domain may be referred to as "MCU Island", "MCU Channel", or "MCU Subsystem".

The Microcontroller Unit Domain (MCU Domain) is a “chip-in-a-chip” concept and it operates using separate clock sources and resets. This allows the MCU Domain to function continuously regardless of the state of the rest of the device, including periods in which the rest of the device is held in reset or powered down. The MCU island integrates communication peripherals such as SPI, I2C, and UART which are expected to be used for safety critical communication, so if the main SoC goes down, the MCU island can communicate this information to the rest of the system.

1.5.1 Arm Cortex-R5F Processor (R5FSS)

The ARM Core Cortex-R5F processor subsystem (R5FSS) supports the following main features:

- Armv7-R architecture
- R5FSS Memory System
  - 32KB Instruction Cache
    - 4x ways
    - SECDED ECC protected per 64 bits
  - Data Cache
    - 4x ways
    - SECDED ECC protected per 32 bits
  - 64KB tightly-coupled memory (TCM) per CPU
    - SECDED ECC protected per 32 bits
    - TCM hard error cache Implemented in CPU
    - Readable/writable from system
    - 32KB TCMA (ATCM)
    - 16KB TCMB0 (B0TCM)
    - 16KB TCMB1 (B1TCM)
- Full-precision Floating Point (VFPv3)
- 16-region Memory Protection Unit (MPU)
- 8 breakpoints, 8 watch points
- CoreSight Debug Access Port (DAP)
- CoreSight ETM-R5 interface (CTI, ETM)
- Performance Monitoring Unit (PMU)
- 32-bit to 36-bit Region-based Address Translation (RAT) on memory access initiators
- Integrated Vectored Interrupt Manager (VIM) per core with 256 Interrupt Inputs each
  - Programmable interrupt priority (4-bit)
  - Programmable interrupt enable mask
  - Software-generated interrupts
  - Synchronous clock domain crossing on all core interfaces

Note

CORE0 has 64KB of TCM.

Note

These details describe a superset of the R5FSS memory configuration. For additional details on device memory availability, please refer to the device-specific Datasheet.

Copyright © 2026 Texas Instruments Incorporated

1.5.2 MCU General Purpose Input/Output Interface (MCU_GPIO)

Integrated in MCU domain: One General Purpose Input/Output (MCU_GPIO) module provides dedicated general-purpose pins that can be configured as either inputs or outputs. the MCU_GPIO module includes these main features:

- Support of 9 banks x 16 GPIO pins
- Support of up to 9 banks of interrupt capable GPIOs
- Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO pin
- Set/clear functionality per individual GPIO pin

1.5.3 MCU Inter-Integrated Circuit Interface (MCU_I2C)

Integrated in MCU domain:One multi-controller Inter-Integrated Circuit (MCU_I2C) interface with the following main features:

- Compliancy to the Philips I2C-bus specification version 2.1
- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- Support of multi-controller transmitter/peripheral receiver and receiver/peripheral transmitter modes
- Built-in FIFOs with programmable size of 8 to 64 bytes for buffered read or write
- 8-bit-wide data access
- Support of Auto Idle, Idle Request/Idle Acknowledge handshake, and Asynchronous Wakeup mechanisms
- Low power consumption

1.5.4 MCU Multi-channel Serial Peripheral Interface (MCU_SPI)

Integrated in MCU domain: Two Multi-channel Serial Peripheral Interface (MCU_SPI) modules where each have the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of MCSPI word lengths, ranging from 4 to 32 bits
- Up to four controller channels, or single channel in receiver mode
- Support of different controller multichannel modes
- Single interrupt line for multiple interrupt source events
- Support of start-bit write command
- Support of start-bit pause and break sequence
- Built-in FIFO available for a single channel

1.5.5 MCU Universal Asynchronous Receiver/Transmitter (MCU_UART)

Integrated in MCU domain: One configurable Universal Asynchronous Receiver/Transmitter (MCU_UART) interface with the following main features:

- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- 16C750 compatible interface
- Baud rates up to 3.6 Mbps with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

1.5.6 MCU Windowed Watchdog Timer/Real Time Interrupt

- Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module providing timer functionality for operation systems and benchmarking code with the following main features:
  - Two independent 64 bit counter blocks
  - Four configurable compare registers for generating operating system ticks

Copyright © 2026 Texas Instruments Incorporated

- Free running counter 0 can be incremented by either the internal pre-scale counter or by an external event
- Selectable RTI clock input (derived from any of the available clock sources)
- Windowed Watchdog Timer (WWDT) feature
- Some RTI modules are pre-dedicated to specific processor cores

1.5.7 MCU TIMER

- Timer modules with support of the following main features:
  - Free running 32-bit upward counter
  - Generates a 1-ms tick with a 32.768-kHz functional clock
  - Interrupts generated on overflow, compare and capture
  - Supported modes of operation: compare and capture, auto-reload and start-stop
  - Programmable divider clock source (2n, where n = [0-8])
  - Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
  - On-the-fly read/write register (while counting) for systems operation and benchmarking code
  - Each odd numbered timer instance may be optionally cascaded with the previous even numbered timer instance to form up to a 64-bit timer

1.5.8 MCU Dual Clock Comparator

- The Dual Clock Comparator (MCU_DCC) module, used to determine the accuracy of a clock signal during the time execution of an application, each having the following main features:
  - Two independent counter blocks count clock pulses from each clock source
  - Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
  - Configurable time base for error signal
  - Error signal generation when one of the clocks is out of spec
  - Clock frequency measurement

1.5.9 Memory Cyclic Redundancy Check

- Memory Cyclic Redundancy Check module used to perform CRC to verify the integrity of a memory system. The MCRC module has the following main feature:
  - Four Channels of CRC Compression based Signature Generation
  - 8, 16, 32, or 64-bit Data Size
  - Maximum Length PSA based on 64-bit Polynomial
  - Programmable 20 bit pattern counter per channel
  - Three Operating Modes: Auto, Semi-CPU, Full CPU
  - MCRC or CPU can perform signature verification for each Channel
  - Timeout Interrupt if CRC is not performed within the time limit

1.5.10 Controller Area Network (MCAN)

Integrated in the domain: One Controller Area Network interfaces (MCAN) supporting both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications and having the following main features:

- Conforms with CAN Protocol version 2.0 part A, B and ISO 11898-1:2015
- Full CAN FD (up to 64 data bytes) support
- SAE J1939 support
- AUTOSAR support
- Up to 32 dedicated transmit buffers and 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit event FIFO, up to 32 elements
- Up to 128 filter elements
- Maskable interrupts, two interrupt lines
- Timestamp Counter

Copyright © 2026 Texas Instruments Incorporated

1.6 Device WKUP Domain

This section describes the modules integrated in the device WKUP domain.

1.6.1 Arm Cortex-R5F Processor (R5FSS)

The ARM Core Cortex-R5F processor subsystem (R5FSS) supports the following main features:

- Armv7-R architecture
- R5FSS Memory System
  - 32KB Instruction Cache
    - 4x ways
    - SECDED ECC protected per 64 bits
  - Data Cache
    - 4x ways
    - SECDED ECC protected per 32 bits
  - 64KB tightly-coupled memory (TCM) per CPU
    - SECDED ECC protected per 32 bits
    - TCM hard error cache Implemented in CPU
    - Readable/writable from system
    - 32KB TCMA (ATCM)
    - 16KB TCMB0 (B0TCM)
    - 16KB TCMB1 (B1TCM)
- Full-precision Floating Point (VFPv3)
- 16-region Memory Protection Unit (MPU)
- 8 breakpoints, 8 watch points
- CoreSight Debug Access Port (DAP)
- CoreSight ETM-R5 interface (CTI, ETM)
- Performance Monitoring Unit (PMU)
- 32-bit to 36-bit Region-based Address Translation (RAT) on memory access initiators
- Integrated Vectored Interrupt Manager (VIM) per core with 256 Interrupt Inputs each
  - Programmable interrupt priority (4-bit)
  - Programmable interrupt enable mask
  - Software-generated interrupts
  - Synchronous clock domain crossing on all core interfaces

Note

CORE0 has 64KB of TCM.

Note

These details describe a superset of the R5FSS memory configuration. For additional details on device memory availability, please refer to the device-specific Datasheet.

1.6.2 Inter-Integrated Circuit Interface (I2C)

Multi-controller Inter-Integrated Circuit (I2C) interface module, with the following main features:

- 1x Instances with open-drain voltage buffers in compliance with the Philips I2C-bus specification version 2.1
- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- 8-bit-wide data access
- Support of multi-controller transmitter/peripheral receiver and receiver/peripheral transmitter modes
- Built-in FIFOs with fixed size of 32 bytes.

Copyright © 2026 Texas Instruments Incorporated

1.6.3 Universal Asynchronous Receiver/Transmitter (UART)

Seven Instances of the configurable Universal Asynchronous Receiver/Transmitter (UART) interface module have the following main features:

- 16C750-compatible interface
- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- Baud-rate from 300 bits/s up to 3.6864 Mbits/s with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

Note

Only one UART instance has support for support full modem control functions. All other UART instances will support only the TX, RX, RTS, and CTS signals.

1.6.4 MCU Error Signaling Module

- Error Signaling Module (MCU_ESM) for safety-related events and/or errors aggregation from throughout the device into one location supports the following main features:
  - Up to 1024 level or pulse error event inputs
  - Selectable low and high priority interrupt error pin prioritization of each error event
  - Single Error Pin output to signal severe device failure to outside world
  - Configurable time base for error signal
  - Triple Redundant Pulse Inputs
  - Two Priority Levels
  - Error Forcing capability
  - Internal redundant flops on safety critical fields

1.6.5 Global Time Counter

- Global Time Counter (GTC) module that can be used for time synchronization and debug trace time stamping with the following main features:
  - 64-bit up counter
  - No rollover during the lifetime of the device
  - Compatible with Armv8 system counter requirements
  - Outputs reflected binary (Gray) encoded timer value for system timer bus distribution to other modules
  - Selectable counter bit output as a push event that can be used by CPTS modules, timers or interface protocols

1.6.6 Windowed Watchdog Timer/Real Time Interrupt

- Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module providing timer functionality for operation systems and benchmarking code with the following main features:
  - Two independent 64 bit counter blocks
  - Four configurable compare registers for generating operating system ticks
  - Free running counter 0 can be incremented by either the internal pre-scale counter or by an external event
  - Selectable RTI clock input (derived from any of the available clock sources)
  - Windowed Watchdog Timer (WWDT) feature
  - Some RTI modules are pre-dedicated to specific processor cores

1.6.7 WKUP_TIMER

- Dual mode timer module with support of the following main features:

Copyright © 2026 Texas Instruments Incorporated

- Free running 32-bit upward counter
- Generates a 1-ms tick with a 32.768-kHz functional clock
- Interrupts generated on overflow, compare and capture
- Supported modes of operation: compare and capture, auto-reload and start-stop
- Programmable divider clock source (2n, where n = [0-8])
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- On-the-fly read/write register (while counting) for systems operation and benchmarking code
- Each odd numbered timer instance may be optionally cascaded with the previous even numbered timer instance to form up to a 64-bit timer
- On-the-fly read/write register (while counting) for systems operation and benchmarking code

1.7 Device Identification

The manufacturer identity, the boundary scan part number, and the silicon revision of the device can be read in the WKUP_CTRL_MMR_CFG0_JTAGID register. See Table 1-1 and Table 1-2 tables for more information.

Table 1-1. Device JTAG ID

WKUP_CTRL_MMR_CFG0_JTAGID Register Field	Value	Comment
[31-28] VARIANT	See Table 1-2	Silicon Revision (SR) identifier.
[27-12] PARTNO	See Table 1-2	Part number for boundary scan.
[11-1] MFG	0x17	Manufacturer identity (TI).
[0] LSB	0x1	Always reads 1.

Table 1-2. Device JTAG ID Values

Silicon Type	VARIANT	PARTNO	WKUP_CTRL_MMR_CFG0_JTAGID Register Value
TDA4VEN SR1.0 TDA4AEN SR1.0 AM67 SR1.0	0x0	0xBBA0	0x0BBA002F

Chapter 2

Memory Map

The SoC level memory map is constructed using a 36b physical address and follows the guideline to put peripherals at 64KB aligned boundary. No virtual address is supported on the SoC level. However, A53 core can support virtual address internally. If software utilizes the address more than 36b, only the lower 36b is used for SoC level address decoding and the upper address bits will be ignored by the SoC. Not all the 36b memory regions are implemented. Any transactions hitting the unimplemented address range will be terminated and routed to null end point to avoid system hang. An interrupt will be asserted and the above transaction will be logged. All the SoC level peripherals and processors use the common SoC memory except the 32b only processors, such as the R5 core. For those processors and peripherals which natively only supports 32b physical address, the Region based Address Translation (RAT) module is used to remap the 32b address into the common 36b SoC address map.

2.1 Processor Memory Map View

The device implements a 36-bit physical address space that is used by the Cortex-A53 subsystem and most other initiators in the system.

Additionally, selected initiators (R5FSS0, MCU_R5FSS0, WKUP_R5FSS0, DMASS0, SMS0, and SA3_SS0) have their own memory maps that are a mix of private endpoints and regions that map to the common 36-bit address space of the SOC.

2.1.1 A53 Memory View

All the A53 cores use the common 36b SoC memory map shown in MAIN Memory Map for its physical address map. Since A53 natively supports up to 44b physical address, if A53 issues any transaction with non-zero upper 8 physical address bits, those upper 8 address bits are ignored by SoC address decoding logic. The A53 uses an MMU to translate the virtual addresses used in operation to the physical addresses issued to the rest of the SoC, see MMU Optimization Note for further details/considerations.

2.1.2 RAT

Since the device is built on 36b physical address, there are memory regions beyond 4GB address, such as DDR data space and debug configuration space. This is not a problem for the ARMv8 core such as A53, since it supports up to 44b physical address. However, the R5 processors natively support only a 32b physical address space. In order to allow these micro controllers accessing the full 36b physical address space, a region based remapping module is dedicated for each processor.

2.1.3 R5FSS Memory View

The device has one single R5F core in the MAIN domain, one single R5F core in the MCU domain, and one single core R5F (Device Manager) in the WKUP domain. The R5F is a native 32b processor, which means the R5F core itself can only generate transactions using 32b address. A dedicated RAT module is integrated for this single core R5F to allow the R5F software to remap the 32b R5F address into the common 36b SoC address.

In addition, the R5F core has its own TCM, which the R5F core can access with its TCM with a single R5F core cycle. Those TCM memories have two sets of address, one set address is used for the R5F core for a single cycle access to those TCM. The second set of address is used by other initiators outside this R5F subsystem to access those TCM. The R5F core shall always use the first set of address to access its TCM. If the R5F core utilizes the second set of address to those TCM, the R5F core will receives an exception, since those transactions will be routed to be terminated by sending them to the null end point.

While the SoC level address for TCM is fixed, the address used by the R5F to access to its own TCM can be remapped by software. By default, the device puts the R5F's ATCM at address 0x0 and the BTCM address at 0x4101_0000.

The MCU R5F has one section of the region dedicated for peripheral access from address 0x0400_0000 to 0x07FF_FFFF. The MAIN R5F and WKUP R5F also have one section of their regions dedicated for peripheral access from address 0x2000_0000 to 0x2FFF_FFFF. These memory regions are treated as normal memory, which can't be cached. The R5F accesses this memory region through a dedicated single-issue interface, and none of the transactions accessing this memory region can be remapped by using RAT module.

The R5F core accesses its own ATCM and BTCM memory directly, and there is no address remapping for those access. All the other access than ATCM, BTCM, and address range 0x0400_0000 to 0x07FF_FFFF from the MCU R5F core, and address range 0x2000_0000 to 0x2FFF_FFFF from the MAIN R5F and WKUP R5F cores go through RAT module, which could be remapped into different address to access the rest of the SoC using the common 36b SoC memory map.

See the R5FSS0 Memory Map, MCU_R5FSS0 Memory Map, and WKUP_R5FSS0 Memory Map.

The common SoC memory map assigns the WKUP R5F's ATCM and BTCM to address 0x7800_0000 and 0x7810_0000, the MCU R5F's ATCM and BTCM to address 0x7900_0000 and 0x7902_0000, and the MAIN R5F's ATCM and BTCM to address 0x7840_0000 and 0x7850_0000. The R5F software can optionally reprogram the its internal ATCM and BTCM address to match the address assigned by the common SoC

Copyright © 2026 Texas Instruments Incorporated

memory map as well. Regardless where the R5F puts its own ATCM and BTCM, the R5F accesses its own ATCM and BTCM directly without going through RAT.

ATCM is by default disabled at address 0x0. BTCM is by default enabled and the default address for BTCM is 0x4101_0000. The base address of MCU VIM is at 0x07FF_0000 and the base address for RAT configuration is at 0x07FE_0000. The base address of MAIN and WKUP VIMs is at 0x2FFF_0000, and the base address for RAT configuration is at 0x2FFE_0000.

All of the MCU R5F transactions can go through RAT for address re-mapping function except the transactions targeted to address range 0x0400_0000 to 0x07FF_FFFF and its own ATCM and BTCM. All of the MAIN and WKUP R5F transactions can go through RAT for address re-mapping function except the transactions targeted to address range 0x2000_0000 to 0x2FFF_FFFF and their own ATCM and BTCM. It is highly recommended only remap the R5F's address range from 0x8000_0000 to 0xFFFF_FFFF to access the target region located at the common memory map between 0x8000_0000 and 0xFFFF_FFFF.

2.2 DDR Memory Region

The device includes two DDR data regions: 2GB at 0x8000_0000 and 30GB at 0x8_8000_0000.

The max size of LPDDR4 is 8GB.

2.3 MMU Optimization Note

The SoC memory map is constructed to enable using MMU granule sizes of 64KB and above by placing most of the system resources on a 64KB address boundary. This also enables isolation of resources and peripherals from individual software processes through unique MMU entries.

The following is a non-exhaustive list of exceptions to this alignment rule:

- Debug SS
- MAIN GPIO0/GPIO1, MCU GPIO
- DCC
- ISC, QOS, Firewall

Resources and peripherals excluded from the 64KB addressing placement are either meant to have a single owner or are logically the same function (such as GPIO).

3.1 System Interconnect Overview

3.1.1 Terminology

- CBASS: this is a crossbar module to provide physical connection among the initiators and targets
- VBUSP interface: a single-issue interface
- VBUSM interface: a multi-issue interface
- Channel ID: channel ID for interface indicates a logical flow. All the transactions with the same channel ID coming from the same initiator interface are consider orthogonal and independent flow.
- OrderID: a 4 bits value associated with each transaction. All the transactions from the same initiator to the same target end point with the same orderID needs to be executed in order. OrderID is also to be used to select real-time and non-real time path for the transaction. OrderID 8-15 reserved for real-time path.
- Asel: Address Selection. Asel can be either used for select a unique memory map or be used to indicate the IO coherent transactions.
- PrivID: indicates the security access group. PrivID is assigned by the ISC block.
- ISC: stands for Initiator Security Control.
- Region based firewall: this is firewall block based on address region.
- Channelized firewall: firewall block with finer granularity down to register level with fixed region size.
- QoS: Quality of Service block is a feature which can be enabled for each CBA initiator port. Each initiator can choose to enable the QoS feature in the CBA configuration file. If an initiator port supports channel ID, the QoS block provides priority and order ID for each channel, otherwise all the transactions from that initiator port share the same priority and order ID value.

CAUTION

Since OrderID is used for ordering purpose in CBASS, changing the order ID when the system is running can cause system deadlock. Therefore, QoS configuration shall be part of the initialization steps, if the application wants to change the QoS setting from the default value.

3.2 Domain Partition

SoC is partitioned into several domains which are connected by interconnect modules.

- **MAIN Domain**: there are multiple interconnect components providing the connectivity among initiators and target interfaces for the processors and peripherals in the MAIN domain. The main application processors, such as A53SS, are located in the MAIN domain.
- **WKUP domain**: R5FSS is located in the WKUP domain. The WKUP domain is active during deepsleep mode.
- **MCU domain**: A microcontroller is located in the MCU domain. The MCU domain can be isolated from the rest of SoC during safety use case.

All modules connected to WKUP_safe interconnect can belong to both MCU domain and WKUP domain depending on the use case. The deep sleep low power mode is controlled by the WKUP Domain. However, when the MCU domain is configured for a safety use case, all of the modules connected to WKUP_safe interconnect will be part of the MCU domain.

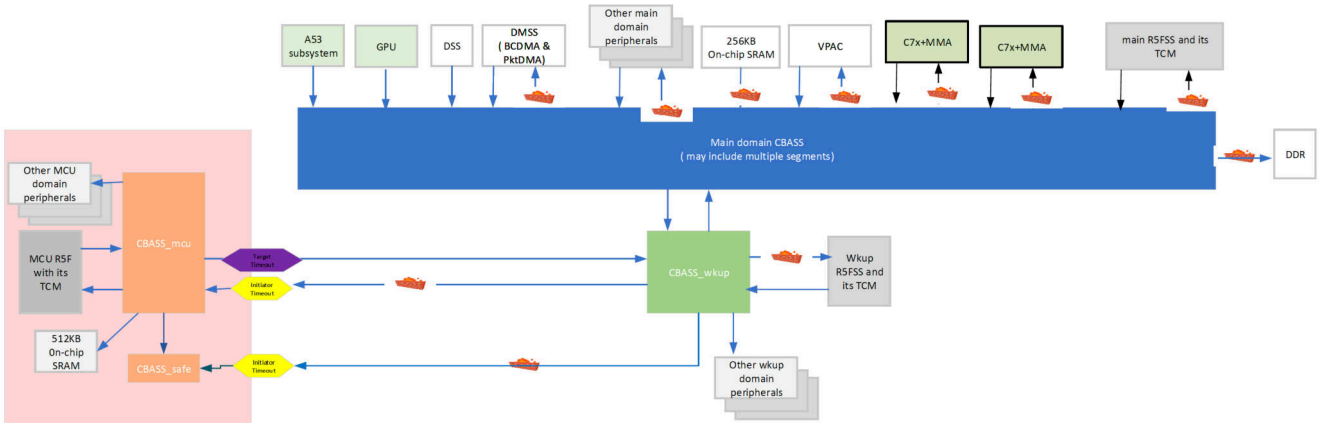

Figure 3-1. System Interconnect Overview

3.3 Initiator/Target Connectivity

All processors and the DMA can communicate with all SoC memory mapped peripherals.

3.4 Interrupt Condition for Interconnect

Each CBASS crossbar IP may generate up to two interrupts:

- default_err_intr: the intent of this interrupt is for debug purposes. Any illegal transactions will trigger this interrupt and the illegal transaction information is logged by CBASS IP.
- default_exp: this interrupt is asserted whenever there is a firewall violation. Only the CBASS IP contains firewall module that can generate this interrupt.

The illegal transactions triggering default_err_intr can be caused by multiple reasons:

- The transaction is sent to a memory region not implemented in CBASS
- The target interface or target peripheral is in disabled state

When CBASS detects an illegal transaction, it terminates the transaction gracefully to avoid a system hang. In addition, the CBASS sends return status back to the initiator with error status. If this illegal transaction is a read transaction, the read data is returned with all zeros. If this illegal transaction is a write transaction, this write transaction is terminated and returns a write error back to initiator. The interrupt and illegal transaction logging can be found in the CBASS's err_regs region.

For any transaction blocked by the firewall, the transaction is terminated gracefully and the initiator will receive error status for the blocked transaction. If this blocked transaction is read, the read data is returned with all zeros. If this blocked transaction is a write transaction, this write transaction is terminated and returns a write error back to the initiator. The default_exp interrupt and the blocked transaction information can be found in the glb_regs region.

Table 3-1. CBASS Interrupt

CBASS Name	default_err_intr Interrupt Supported	default_exp Interrupt Supported
CBASS0	Yes	Yes
MCU_CBASS0	Yes	No
CBASS_INFRA1	Yes	Yes
CBASS_FW0	Yes	No
CBASS_DBG0	Yes	No
CBASS_IPCSS0	Yes	Yes
CBASS_CENTRAL2	Yes	Yes
CBASS_MCASP0	Yes	No
WKUP_CBASS0	Yes	Yes

3.4.1 Register MMR for default_err_intr

Each CBASS supports default_err_intr containing an err_regs region, which includes the following registers:

Address Offset	Register Mnemonic	Register Name
0x0	PID	Revision Register
0x4	DESTINATION_ID	Destination ID Register
0x24	EXCEPTION_LOGGING_HEADER0	Exception Logging Header 0 Register
0x28	EXCEPTION_LOGGING_HEADER1	Exception Logging Header 1 Register
0x2c	EXCEPTION_LOGGING_DATA0	Exception Logging Data 0 Register
0x30	EXCEPTION_LOGGING_DATA1	Exception Logging Data 1 Register
0x34	EXCEPTION_LOGGING_DATA2	Exception Logging Data 2 Register
0x38	EXCEPTION_LOGGING_DATA3	Exception Logging Data 3 Register
0x50	ERR_INTR_RAW_STAT	Global Interrupt Raw Status Register
0x54	ERR_INTR_ENABLED_STAT	Global Interrupt Enabled Status Register
0x58	ERR_INTR_ENABLE_SET	Interrupt Enable Set Register
0x5c	ERR_INTR_ENABLE_CLR	Interrupt Enable Clear Register
0x60	ERR_EOI	EOI Register

PID (Revision Register) is located at offset 0x0. The following shows the definition of each field of this register.

The Revision Register contains the major and minor revisions for the module.

Bit	Name	Type	Reset	Description
31:30	scheme	r	0x1	PID register scheme
29:28	bu	r	0x2	Business Unit: 10 = Processors
27:16	func	r	0x600	Module ID
15:11	rtl	r	0x6	RTL revision. Will vary depending on release.
10:8	major	r	0x1	Major revision
7:6	custom	r	0x0	Custom
5:0	minor	r	0x2	Minor revision

DESTINATION_ID (Destination ID Register) has offset 0x4.

The Destination ID Register defines the destination ID value for error messages.

Bit	Name	Type	Reset	Description
31:8	reserved	r	0x0	Reserved
7:0	dest_id	rw	0x0	The destination ID.

Copyright © 2026 Texas Instruments Incorporated

EXCEPTION_LOGGING_HEADER0 (Exception Logging Header 0 Register), (0x24)

The Exception Logging Header 0 Register contains the first word of the header.

Bit	Name	Type	Reset	Description
31:24	type_f	r	0x0	Type. 7 = CBASS.
23:8	src_id	r	0x0	Source ID. Always 0.
7:0	dest_id	r	0x0	Destination ID.

EXCEPTION_LOGGING_HEADER1 (Exception Logging Header 1 Register) has offset 0x28.

The Exception Logging Header 1 Register contains the second word of the header.

Bit	Name	Type	Reset	Description
31:24	group	r	0x0	Group. Always 0.
23:16	code	r	0x0	Code. 0 = CBASS decode error.
15:0	reserved	r	0x0	Reserved

EXCEPTION_LOGGING_DATA0 (Exception Logging Data 0 Register) has offset 0x2c.

The Exception Logging Data 0 Register contains the first word of the data.

Bit	Name	Type	Reset	Description
31:0	addr_l	r	0x0	Address lower 32 bits.

EXCEPTION_LOGGING_DATA1 (Exception Logging Data 1 Register), (0x30)

The Exception Logging Data 1 Register contains the second word of the data.

Bit	Name	Type	Reset	Description
31:16	reserved	r	0x0	Reserved
15:0	addr_h	r	0x0	Address upper 16 bits.

EXCEPTION_LOGGING_DATA2 (Exception Logging Data 2 Register has offset 0x34.

The Exception Logging Data 2 Register contains the third word of the data.

Bit	Name	Type	Reset	Description
31:28	reserved	r	0x0	Reserved
27:16	routeid	r	0x0	Route ID.
15:14	reserved	r	0x0	Reserved
13	write	r	0x0	Write.
12	read	r	0x0	Read.
11	debug	r	0x0	Debug.
10	cacheable	r	0x0	Cacheable.
9	priv	r	0x0	Priv.
8	secure	r	0x0	Secure.
7:0	priv_id	r	0x0	Priv ID.

EXCEPTION_LOGGING_DATA3 (Exception Logging Data 3 Register) has offset 0x38.

The Exception Logging Data 3 Register contains the fourth word of the data.

Bit	Name	Type	Reset	Description
31:10	reserved	r	0x0	Reserved

Copyright © 2026 Texas Instruments Incorporated

Bit	Name	Type	Reset	Description
9:0	bytecnt	r	0x0	Byte count.

ERR_INTR_RAW_STAT (Global Interrupt Raw Status Register), (0x50)

The interrupt raw status register indicates if there is null interrupt regardless of interrupt enable

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	intr	rw1ts	0x0	Level Interrupt status

ERR_INTR_ENABLED_STAT (Global Interrupt Enabled Status Register), (0x54)

The interrupt status register is gated by the interrupt enable

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	enabled_intr	rw1tc	0x0	Level Enabled Interrupt status

ERR_INTR_ENABLE_SET (Interrupt Enable Set Register), (0x58)

Only when this register is set, null access will cause interrupt to be generated.

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	intr_enable_set	rw1ts	0x0	Interrupt Enable Set Register

ERR_INTR_ENABLE_CLR (Interrupt Enable Clear Register), (0x5c)

Setting this register disables the null interrupt generation

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	intr_enable_clr	rw1tc	0x0	Interrupt Enable Clear Register

ERR_EOI (EOI Register), (0x60)

Writing to EOI Register indicates that current interrupt has been serviced which then allows next interrupt to be generated

Bit	Name	Type	Reset	Description
31:16	reserved	r	0x0	Reserved
15:0	eoi_wr	rw	0x0	End Of Interrupt Register

3.4.2 Register MMR for default_exp

All of the registers for default_exp_intr are located in the glb_regs region of the CBASS which supports this feature. For each glb_reg region, the following registers are supported.

Table 3-2. glb_regs for default_exp_intr

Address Offset	Register Mnemonic	Register Name
0x0	PID	Revision Register
0x4	DESTINATION_ID	Destination ID Register
0x20	EXCEPTION_LOGGING_CONTROL	Exception Logging Control Register
0x24	EXCEPTION_LOGGING_HEADER0	Exception Logging Header 0 Register
0x28	EXCEPTION_LOGGING_HEADER1	Exception Logging Header 1 Register

Copyright © 2026 Texas Instruments Incorporated

Table 3-2. glb_regs for default_exp_intr (continued)

Address Offset	Register Mnemonic	Register Name
0x2c	EXCEPTION_LOGGING_DATA0	Exception Logging Data 0 Register
0x30	EXCEPTION_LOGGING_DATA1	Exception Logging Data 1 Register
0x34	EXCEPTION_LOGGING_DATA2	Exception Logging Data 2 Register
0x38	EXCEPTION_LOGGING_DATA3	Exception Logging Data 3 Register
0x40	EXCEPTION_PEND_SET	Exception Logging Pending Set Register
0x44	EXCEPTION_PEND_CLEAR	Exception Logging Pending Clear Register

The Revision Register contains the major and minor revisions for the module.

Bit	Name	Type	Reset	Description
31:30	scheme	r	0x1	PID register scheme
29:28	bu	r	0x2	Business Unit: 10 = Processors
27:16	func	r	0x600	Module ID
15:11	rtl	r	0x6	RTL revision. Will vary depending on release.
10:8	major	r	0x1	Major revision
7:6	custom	r	0x0	Custom
5:0	minor	r	0x2	Minor revision

The Destination ID Register defines the destination ID value for error messages.

Bit	Name	Type	Reset	Description
31:8	reserved	r	0x0	Reserved
7:0	dest_id	rw	0x0	The destination ID.

The Exception Logging Control Register controls the exception logging.

Bit	Name	Type	Reset	Description
31:2	reserved	r	0x0	Reserved
1	disable_pend	rw	0x0	Disables logging pending when set.
0	disable_f	rw	0x0	Disables logging when set.

The Exception Logging Header 0 Register contains the first word of the header.

Bit	Name	Type	Reset	Description
31:24	type_f	r	0x0	Type.
23:8	src_id	r	0x0	Source ID.
7:0	dest_id	r	0x0	Destination ID.

The Exception Logging Header 1 Register contains the second word of the header.

Bit	Name	Type	Reset	Description
31:24	group	r	0x0	Group.
23:16	code	r	0x0	Code.
15:0	reserved	r	0x0	Reserved

The Exception Logging Data 0 Register contains the first word of the data.

Copyright © 2026 Texas Instruments Incorporated

Bit	Name	Type	Reset	Description
31:0	addr_l	r	0x0	Address lower 32 bits.

The Exception Logging Data 1 Register contains the second word of the data.

Bit	Name	Type	Reset	Description
31:16	reserved	r	0x0	Reserved
15:0	addr_h	r	0x0	Address upper 16 bits.

The Exception Logging Data 2 Register contains the third word of the data.

Bit	Name	Type	Reset	Description
31:28	reserved	r	0x0	Reserved
27:16	routeid	r	0x0	Route ID.
15:14	reserved	r	0x0	Reserved
13	write	r	0x0	Write.
12	read	r	0x0	Read.
11	debug	r	0x0	Debug.
10	cacheable	r	0x0	Cacheable.
9	priv	r	0x0	Priv.
8	secure	r	0x0	Secure.
7:0	priv_id	r	0x0	Priv ID.

The Exception Logging Data 3 Register contains the fourth word of the data.

Bit	Name	Type	Reset	Description
31:10	reserved	r	0x0	Reserved
9:0	bytecnt	r	0x0	Byte count.

The Exception Logging Pending Set Register allows to set the pend signal.

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	pend_set	rw1ts	0x0	Write a 1 to set the exception pend signal.

The Exception Logging Pending Clear Register allows to clear the pend signal.

Bit	Name	Type	Reset	Description
31:1	reserved	r	0x0	Reserved
0	pend_clr	rw1tc	0x0	Write a 1 to clear the exception pend signal.

3.5 Coherency Features

3.5.1 IO Coherency Support

There are 4 bits for ASEL sideband signals. These enable a single SoC to support up to 16 different memory maps. ASEL can be used for two different purposes: it can be used as an indicator of a different memory map (ASEL value 1-12) or indicate transactions requires IO coherency (ASEL value 13-14). ASEL value can be

Copyright © 2026 Texas Instruments Incorporated

configured either through DMA configuration if the transaction is initiated by DMSS or UTC or DRU or configured through QoS MMR for the initiator who generates the transactions. Refer to QoS Programming Guide.

ASEL value of 0

- Default for the SoC Memory Map
- Will use the transaction address for memory map decoding

Non-zero ASEL values

- Assigned to a target end point, which can be used to bypass the normal address decoding
- Can be assigned to the transactions through either DMA configuration for both BCDMA and pktDMA transaction or through the QoS block inserted for each initiator interface
- ASEL value 1: Reserved for PCIe if supported by the device. Otherwise, transactions will be routed to the null end point for graceful termination.
- ASEL values 2-13: Transactions will be routed to the null end point for graceful termination.
- ASEL values 14-15: Dedicated routing to A53SS ACP Interface for transactions that require IO Coherency.
  - Write transactions with ASEL=14 cause A53SS L2 cache allocation: for cache warming feature
  - Write transactions with ASEL=15 do not cause A53SS L2 cache allocation
  - Read transactions with ASEL=14 and 15 do not cause L2 cache allocation
  - All the transactions to ACP port can be protected by firewall if firewall is inserted by the SoC level interconnect

The A53SS checks security on the transactions from the ACP port. However, it does not include supervisor or user mode checks. If different permissions are needed for the supervisor or user mode transactions, different access permissions can be granted using the region-based firewall.

The transactions initiated by the microcontroller do not support IO coherency.

3.6 Performance Tuning

3.6.1 Latency Reduction

The auto clock gating feature of WKUP domain peripherals is enabled by default.

The disabling of auto clock gating may result in improved performance.

The auto clock gating control can be modified during device initialization time through registers CLKGATE_CTRL0 and CLKGATE_CTRL1 in the WKUP_CTRL_MMR domain.

3.6.2 Using Quality of Service (QoS) MMR

The majority of the initiator has a dedicated QoS block to provide the configurability of the transaction characteristic, such as OrderID, priority/epriority, asel and etc. The user can utilize the OrderID and priority/epriority fields to fine tune the performance.

Each transaction in the system carries 3 bits priority information. The priority information is used for interconnect for arbitration decision, which implements typical priority based round robin. Priority value 0x0 is the highest priority, while 0x7 is the lowest priority. By default, QoS has priority value set to 0x7(lowest priority). The priority and epriority can be changed through the QoS block for each initiator.

Some of the modules such as DSS is able to adjust the priority of the transaction based on the system congestion condition. But majority of the transactions have static priority level set by the QoS block. But the priority setting through QoS block can be tuned to fit certain use case scenarios.

CAUTION

Priority, orderID and asel value from the QoS block shall only be modified as part of the initialization steps, when the SoC is idle. Changing the QoS block configuration during the run time is prohibited, and may cause system error or other undefined behavior.

3.6.2.1 QoS MMR Programming Guide

The QoS MMR is integrated as part of data plane interconnect to provide programmability of priority, orderID and QoS sideband signals for each initiator port in the data plane. Currently the QoS sideband signal is not used for any routing or schedule purpose. For most of the initiator ports, it has only one setting of the orderID and QoS field. For the initiator port supports with multiple channels, the transactions in each channel can be programmed to have different sets of priority, orderID and QoS. The orderID is a four-bit field value. All the transactions coming from the same initiator ports with the same orderID expect to receive the read data in order.

In the previous generation of the interconnect, how the traffic is split among parallel paths to the same end points was hard coded. The traffic from a certain initiator port was hard coded to choose one of the parallel paths. Due to the nature of hard coded, the system could not load balance based on the use case. The current generation of interconnect removes this limitation by splitting traffic using the OrderID value. Since the orderID value for the traffic from each initiator port is programmable, the user can load balance based on the use case scenario.

Each target port in each SCR has its own arbiter. The SoC interconnect arbitration is based on priority. For the ports with equal priority, the arbiter uses round robin to break the tie.

DDR EMIF (External Memory Interface) also uses orderID to maintain transaction ordering. All transactions with the same orderID sent to the EMIF will be executed in order. In order to maximize the EMIF performance, the user shall carefully use the full range of 16 orderID values. Therefore, the EMIF can utilize its re-ordering mechanism to improve the EMIF utilization.

Inside the EMIF controller, registers map CBA priority to AXI priority. The EMIF controller schedules transactions using a strict priority scheme based on AXI priority. In order to maximize the DDR utilization to reduce the memory page open/close and read and write turn around penalty, it is suggested to map to a single AXI priority.

3.7 Interconnect Debugging Feature

Interconnect routes the transaction to null end point for graceful termination under the following situation:

- There is no physical connection between initiator and target end points
- Or target interface is in disabled state
- Or the transaction is sent to an unpopulated address

The null end point returns the error status back to the initiator to prevent the interconnect hang. At the same time, the interconnect module logs this transaction information in err_reg region and issues an error interrupt (default_err_intr). This default_err_intr is sent to all of the application processors for debug purposes.

If the transaction is sent to a valid target interface, however the firewall in front of the target interface can prohibit the transaction, the transaction will be logged in the glb_regs region and the interconnect will assert a default_exp interrupt.

3.8 Quality of Service (QoS) Block

CBASS arbitrates the transaction based on priority from high to low. If the transactions going to the same end point have the same priority, then the CBASS uses round robin method for these transactions.

In the CBASS with parallel paths, orderID is used to determine how the transactions are forwarded to those parallel paths. The parallel paths are defined as two target interfaces with the exact same memory map assignment.

By default, all the target interfaces have a certain address assigned and CBASS routes the transactions based on this address. However, some of the special target interfaces can be routed through a different mechanism using the ASEL signal, such as MPU A53SS's ACP interface and PCIe target interfaces.

By default, the majority of the transactions default to the lowest priority level, ASEL value to zero and orderID to zero. The transactions from BCDMA and pktDMA have those attributes as part of the DMA configuration. ASEL value is part of the address information passed to the DMA engine. It is normally specified in descriptors such as host packet descriptor and host buffer descriptor for pktDMA, and Transfer Request (TR) packet descriptor for BCDMA. The priority and orderID information can be configured through each DMA channel's priority control register.

For the rest of the initiators, the CBASS IP provides QoS block to allow the user to program the transaction's attributes such as priority level, ASEL coding and orderID.

Copyright © 2026 Texas Instruments Incorporated

The QoS block programming is through CBASS's qos_regs region. Each initiator, except the BCDMA, pktDMA, and debugss, has an MMR to allow the user to set the priority, ASEL, and orderID value. There is another exception on priority setting. The display IP implements dynamic priority schedule based on the FIFO threshold. The QoS block inside CBASS does not have the ability to overwrite the priority value coming from the display IP.

Section *QoS Summary Table* shows the mapping between initiators and QoS block physical addresses.

Each QoS block has one 4B MAP register per channel that allows the user to program ASEL, orderID, and priority. The first MAP register is at offset 0x100 and the MAP register for channel X is located at offset 0x100 + 400x. See *QoS Block MMR*.

For any write to address range 0x4500_0000 to 0x45FF_FFFF, it is recommended to read back the value after the write to make sure the write landed. The registers in this regions are mainly for firewall configuration, ISC/DMA credential configuration, QoS MMR configuration.

On QoS MMR configuration, in order to configure certain transaction to be the highest priority, the priority field needs to be set to zero for that transaction. In order to make sure that priority field is indeed to set to zero, the following sequence should be followed:

1. Read the priority field, if it is non-zero value, follow a write to overwrite priority field to be 0x0.
2. If read back priority field is zero, write to QoS MMR register to set priority field to be 0x7. Read back the same priority field. If the read back value is 0x7, write to QoS MMR register to set priority field to be 0x0. If the read back value is 0x0, it means this register is not implemented and priority setting is not working.

3.9 Route ID

The route ID is used by the interconnect to route return status and data back to the transaction initiator. Each initiator has one or multiple unique route IDs assigned to it. The route ID has no other usage. There are no software controls for the route ID. The initiator-to-route-ID assignment is shown in Table 3-19.

3.10 ISC and Firewall

There are two basic building blocks to achieve security isolation on the SoC level: firewall block and ISC block.

3.10.1 Initiator-Side Security Controls (ISC)

The purpose of the ISC block is to provide a mechanism to either add or overwrite the attributes of the transaction, such as privID, priv, and secure. Each transaction in the system carries those attributes, either driven internally by the IP, or added/modified by the ISC block for that initiator.

All the transactions coming from pktDMA, BCDMA, and DMSS_crypto, the privID, priv, and secure attributes are driven internally by the DMA engine. There is no ISC block to override the values for these transactions. For the transactions from pktDMA, BCDMA, and XLCDMA, the secure, priv, and privID values are determined by the credential register for each DMA flow.

Transactions from all other initiators, attributes can be added or overridden by the ISC block.

The majority of the ISC blocks only contain one region, therefore all the transactions through that ISC block share the same ISC setting. There are a few ISC blocks supporting either multiple channels or multiple regions. The default setting for those ISC blocks with multiple channels, or multiple regions, are the same. However, the transaction attributes can be modified in a finer granularity by utilizing the multiple channel/region mode. If the channel mode is enabled, the starting address and the end address MMRs should be programmed to the starting and end channel number for that ISC region. If the region mode is enabled, the starting and end address MMRs are the address range the transactions are sent to.

Table 3-20 shows the default setting for privID/priv setting. It is recommended not to change those settings except some specific conditions.

3.10.1.2 ISC Registers

CBASS ISC Registers are described in Table 3-21.

Each ISC block contains a set of MMRs for each region/channel: Control MMR, start address, and end address. If an ISC block is configured to have x region/channels, this ISC block contains x+1 sets of MMRs.

Table 3-21. ISC Registers

Address Offset	Register Mnemonic	Register Name
(b*0x20), b=0..31	REGION[b]_CONTROL	ISC a Region b Control Register
(b*0x20)+0x10, b=0..31	REGION[b]_START_ADDR_L	ISC a Region b Start Address Low Register
(b*0x20)+0x14, b=0..31	REGION[b]_START_ADDR_H	ISC a Region b Start Address High Register
(b*0x20)+0x18, b=0..31	REGION[b]_END_ADDR_L	ISC a Region b End Address Low Register

Copyright © 2026 Texas Instruments Incorporated

Table 3-21. ISC Registers (continued)

Address Offset	Register Mnemonic	Register Name
(b*0x20)+0x1c, b=0..31	REGION[b]_END_ADDR_H	ISC a Region b End Address High Register

Each ISC can be configured in one of two modes: region mode and channel mode.

When the region mode is configured, the start and end address MMRs shall be programmed with an SoC address range.

When ISC is configured as channel mode, the start and end address MMRs shall be programmed using channel number.

Each region and channel can be configured to determine whether to overwrite or add values for priv, privID, and secure attributes. A default value for the control MMR, located at offset x*0x20, is used so that transactions do not map to a valid region.

The following is the SW sequence to modify the default ISC setting for region/channel b:

- If channel mode is needed, set ch_mode field to 0x1. Program the start and end address MMRs to be the channel ID
- If region mode is needed, set ch_mode field to be 0x0. Program the start and the end address MMRs to match the address range.
- Set enable field to be 0xA
- If lock field is set to 0x1, then this control MMR can't be changed until it is reset to 0x0
- PrivID: if the transaction carries privID attribute, ISC can either direct use the privID attribute from the transaction by setting the pass field to 0x0, or overwrite it using the new value define in this control register by setting the pass field to be 0x1. If the transaction does not have privID attribute, the ISC will add the privID to this transaction, regardless of the value in the pass field.
- Secure attribute: the transaction can either be forced to be non-secure mode by setting nonsec field to be 0x1, or force the transaction to be secure by setting sec field to be 0xA, or just pass through the secure attribute if the original transaction carries secure attribute. For an initiator which does not provide secure attributes, it is default set to non-secure.
- Priv attribute: by default priv attribute is not set. ISC can be used to overwrite priv attribute either to be user mode by setting nopri field to 0xF, or supervisor mode by setting priv field to be 0xF

3.10.2 Transaction Attributes for BCDMA and PktDMA Transactions

Quality of Service (QoS) Block and Initiator-Side Security Controls (ISC) provide information on how to set up the attributes on the generic transaction. But the BCDMA and pktDMA transactions do not rely on the ISC block and QoS block to set the transaction attributes. Instead, those attributes are determined by the various DMA configuration registers:

Table 3-22. BCDMA and PktDMA Transaction Attributes

	How to configure BCDMA/PktDMA Transactions	Link
ASEL	Descriptors: host packet descriptor and host buffer descriptor for pktDMA and Transfer Request (TR) descriptors for BCDMA	See DMASS Transfer Request Descriptor
priority	Channel priority control register	See Channel Priority Control Register
orderID	Channel priority control register	
secure	Flow credential registers	See Flow Credential Register
priv	Flow credential registers	
privID	Flow credential registers	
atype	Channel configuration MMR. Fixed to 2b'00.	

3.10.3 Firewall Block

There are two types of firewall: region based firewall and channelized firewall.

Copyright © 2026 Texas Instruments Incorporated

The channelized firewall is only implemented to protect the registers which control the power domain and LPSC for security enclave. User can’t modify the channelized firewall setting.

Region based firewalls are inserted at the target end point in the interconnect. Normally a group of the target interfaces share one region-based firewall. Each region-based firewall has its unique configuration of:

- FWID: this is a unique index of firewall block.
- Number of protected regions: this is to indicate how many protected regions users can define and program
- Memory regions behind this firewall: transactions sent to those memory regions will go through this firewall protection

Majority of the memory regions in the SoC are protected by region-based firewalls, except the public boot ROM, debug cell, and STM.

Region Based Firewalls shows the firewall summary on SoC.

3.10.3.2 Region Based Firewall Programming

Each firewall block can be configured to support multiple regions and each region can be configured individually.

See Region Based Firewalls.

4.1 Memory Controllers

4.1.1 DDR32 Subsystem (DDR32SS)

This section contains the integration details for the 32-bit DDR module on this device. For further information, see the *DDR32 Subsystem (DDR32SS)* section of the *Memory Controllers* chapter.

4.1.1.1 DDR32SS Unsupported Features

The following features are not supported on this family of devices:

- DDR3, DDR3L, DDR3U, and LPDDR4x Devices
- Two independent 16-bit channels for LPDDR4
- DIMMS
- Data bus obfuscation / data encryption
- Fail-safe reset I/O to maintain reset state during SoC power OFF
- Automatic periodic scrubbing of SDRAM for ECC
- Coherence of transactions arriving across the RT and NRT bus interfaces
- Maximum of 17 row bits are supported for LPDDR4. LPDDR4 with 18 row bits are not supported
- LPDDR4 devices with byte mode die configurations
- The ECC engine of the DDR controller
- 1T command timing (only 2T timing is supported)

4.1.1.2 ddr32ss Integration

Table 4-1. DDR32SS Module Allocations

Instance	MAIN	MCU	WKUP
DDR32SS0	✓		

Table 4-2. Clock Integration for ddr32ss

Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
DDR32SS0	DDRSS_DDR_PLL_CLK	MAIN_PLL12_HSDIV0_CLKOUT		None
DDR32SS0	PLL_CTRL_CLK	MAIN_SYSCLK0		None

Table 4-3. Hardware Requests for ddr32ss

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
DDR32SS0	DDR32SS0_ddrss_controller_0	GICSS0_spi_151	GICSS0	DDR32SS0 interrupt request	level

4.1.2 MSRAM8KX256E

This section contains the integration details for the MSRAM8KX256E module on this device.

4.1.2.1 MSRAM8KX256E Unsupported Features

The following features are not supported on this family of devices:

- Coherency
- Exclusive access
- Cache line wrap addressing mode

4.1.2.2 msram8kx256e Integration

Table 4-4. MSRAM8KX256E Module Allocations

Instance	MAIN	MCU	WKUP
msram8kx256e0	✓		

Table 4-5. Integration Attributes for msram8kx256e

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies

4.3.2 Video Encoder/Decoder (CODEC)

This section contains the integration details for the CODEC module on this device. For further information, see the *Video Encoder/Decoder (CODEC)* section of the *Processors and Accelerators* chapter.

4.3.2.1 CODEC Unsupported Features

The following features are not supported on this family of devices:

- YUV422 format output in Decode
- YUV422 10-bit support
- Slice-level processing/synchronization
- MMU/RAT for > 32-bit address support. Address mapping > 32-bit can be accomplished by IP assigning the higher addresses for frame buffers to support 36-bit.

4.3.3.2 Arm Cortex R5F Subsystem (R5FSS)

This section contains the integration details for the R5FSS module on this device. For further information, see the Arm Cortex R5F Subsystem (R5FSS) section of the Processors and Accelerators chapter.

4.3.3.2.1 R5FSS Unsupported Features

The following features are not supported on this family of devices:

- Lockstep
- 32-bit VBUSM Initiator Peripheral Port normal or virtual
- BTCM0 / BTCM1 interleaving on MSB option

4.3.3.2.2 R5FSS Integration

4.4 Interprocessor Communication

4.4.1 Mailbox

This section contains the integration details for the Mailbox module on this device. For further information, see the *Mailbox* section of the I*nterprocessor Communication* chapter.

4.4.1.1 Mailbox Unsupported Features

The following features are not supported on this family of devices:

- 'User' protection of mailbox in hardware. If required, must be implemented by software.

4.4.1.2 mailbox Integration

4.4.2 Spinlock

This section contains the integration details for the Spinlock module on this device. For further information, see the *Spinlock* section of the *Interprocessor Communication* chapter.

4.4.2.1 SPINLOCK Unsupported Features

The following features are not supported on this family of devices:

- ARM architectural Spinlock instructions (LDREX,STREX)
- Any use model other than binary mutex (for example, counting semaphore, lockless programming): Spinlock MMR is a single binary 0,1 implemented by a state machine.
- 64-bit accesses: Spinlock MMRs are aligned on 32-bit boundaries meaning a 64-bit access affects the state of 2 Spinlocks.

4.4.2.2 SPINLOCK Integration

4.6.2 Generic Interrupt Controller Subsystem (GICSS)

This section contains the integration details for the GICSS modules on this device. For Further information, see the *Generic Interrupt Controller (GICSS)* section of the *Interrupts* chapter.

4.6.2.1 GICSS Unsupported Features

The following features are not supported on this family of devices:

- GICv2 backwards compatibility
- AWID-based LPI mapping

4.6.2.2 gicss Integration

4.7.1 Data Movement Subsystem (DMSS)

This section contains the integration details for the DMSS module on this device. For Further information, see the Data Movement Subsystem (DMSS) section of the Data Movement Architecture chapter

4.7.1.1 DMSS Unsupported Features

The following features are not supported on this family of devices:

- Ring Accelerator QM and CREDENTIAL Modes

4.7.1.2 DMASS Integration

Table 4-246. DMASS Module Allocations

Instance	MAIN	MCU	WKUP
DMASS0	✓		
DMASS1	✓		

4.7.1.3 DMASS_CBASS_0 Integration

Table 4-247. DMASS_CBASS_0 Module Allocations

Instance	MAIN	MCU	WKUP
DMASS0_CBASS_0	✓		

4.7.1.4 DMASS_COMMON_0 Integration

Table 4-248. DMASS_COMMON_0 Module Allocations

Instance	MAIN	MCU	WKUP
DMASS0_COMMON_0	✓		
DMASS1_COMMON_0	✓		

4.7.1.5 DMASS_ECC_AGGR_0 Integration

Table 4-249. DMASS_ECC_AGGR_0 Module Allocations

Instance	MAIN	MCU	WKUP
DMASS0_ECC_AGGR_0	✓		
DMASS1_ECC_AGGR_0	✓		

Table 4-250. Clock Integration for DMASS_ECC_AGGR_0

Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
DMASS0_ECC_AGGR_0	FICLK	MAIN_SYSCLK0/2		None
DMASS1_ECC_AGGR_0	FICLK	MAIN_SYSCLK0		None

Table 4-251. Hardware Requests for DMASS_ECC_AGGR_0

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
DMASS0_ECC_AGGR_0	DMASS0_ECC_AGGR_0_ecc_corrected_err_level_0	ESM0_esm_lvl_event_9	ESM0	DMASS0_ECC_AGGR_0 interrupt request	level

4.8.2 Multichannel Audio Serial Port (MCASP)

This section contains the integration details for the MCASP module on this device. For further information, see the *Multichannel Audio Serial Port (MCASP)* section of the *Peripherals* chapter.

4.8.2.1 MCASP Unsupported Features

The following features are not supported on this family of devices:

- Muting output (AMUTE)
- Muting input (AMUTEIN)
- Instances may not support all pin options. See device specific Datasheet for details on pin support of each MCASP instance.

4.9 General Connectivity

4.9.1 General Purpose Input/Output (GPIO)

This section contains the integration details for the GPIO modules on this device. For further information, see the *General-Purpose Interface* section of the *Peripherals* chapter.

4.9.1.1 GPIO Unsupported Features

The following features are not supported on this family of devices:

- The following apply to MCU_GPIO0:
  - MCU_GPIO0_[143:24] are not pinned out.
  - Interrupts [143:24] are not pinned out.
  - Bank Interrupts [8:2] are not pinned out.
- The following apply to GPIO0:
  - GPIO0_[143:87] are not pinned out.
  - Interrupts [143:92] are not pinned out.
  - Bank Interrupts [8:6] are not pinned out.
- The following apply to GPIO1:
  - GPIO1_[143:73], GPIO1_[41:32] are not pinned out.
  - Interrupts [143:72] are not pinned out
  - Bank Interrupts [8:4] are not pinned out.

4.9.1.2 GPIO Integration

Table 4-274. GPIO Module Allocations

Instance	MAIN	MCU	WKUP
GPIO0	✓		
GPIO1	✓		
MCU_GPIO0		✓	

Table 4-275. Integration Attributes for GPIO

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
GPIO0	PSC0	GP_CORE	LPSC_main_alwayson	0	ON	NO	
GPIO1	PSC0	GP_CORE	LPSC_main_alwayson	0	ON	NO	
MCU_GPIO0	WKUP_PSC0	GP_core_CTL_MCU	LPSC_mcu_alwayson	0	ON	NO	

Table 4-276. Clock Integration for GPIO

Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
GPIO0	FICLK	MAIN_SYSCLK0/4		functional and interface clock
GPIO1	FICLK	MAIN_SYSCLK0/4		functional and interface clock
MCU_GPIO0	FICLK	MCU_SYSCLK0/4	MCU_CTRL_MMR_CFG0_MCU_GPIO_CLKSEL[1:0]=0	functional and interface clock
MCU_GPIO0	FICLK	LFOSC0 (INSTANCE)/4	MCU_CTRL_MMR_CFG0_MCU_GPIO_CLKSEL[1:0]=1	functional and interface clock
MCU_GPIO0	FICLK	CLK_32K_RC/4	MCU_CTRL_MMR_CFG0_MCU_GPIO_CLKSEL[1:0]=2	functional and interface clock

Table 4-276. Clock Integration for GPIO (continued)

Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
MCU_GPIO0	FICLK	CLK_12M_RC/4	MCU_CTRL_MMR_CFG0_MCU_GPIO_CLKSEL[1:0]=3	functional and interface clock

Table 4-277. Reset Integration for GPIO

Module Instance	Source	Description
GPIO0	PSC0	GPIO0 reset
GPIO1	PSC0	GPIO1 reset
MCU_GPIO0	WKUP_PSC0	MCU_GPIO0 reset

Table 4-278. Hardware Requests for GPIO

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
GPIO0	GPIO0_gpio_0	MAIN_GPIOMUX_INTROUTER0_in_0	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_1	MAIN_GPIOMUX_INTROUTER0_in_1	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_2	MAIN_GPIOMUX_INTROUTER0_in_2	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_3	MAIN_GPIOMUX_INTROUTER0_in_3	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_4	MAIN_GPIOMUX_INTROUTER0_in_4	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_5	MAIN_GPIOMUX_INTROUTER0_in_5	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_6	MAIN_GPIOMUX_INTROUTER0_in_6	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_7	MAIN_GPIOMUX_INTROUTER0_in_7	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_8	MAIN_GPIOMUX_INTROUTER0_in_8	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_9	MAIN_GPIOMUX_INTROUTER0_in_9	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_10	MAIN_GPIOMUX_INTROUTER0_in_10	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_11	MAIN_GPIOMUX_INTROUTER0_in_11	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_12	MAIN_GPIOMUX_INTROUTER0_in_12	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_13	MAIN_GPIOMUX_INTROUTER0_in_13	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_14	MAIN_GPIOMUX_INTROUTER0_in_14	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_15	MAIN_GPIOMUX_INTROUTER0_in_15	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_16	MAIN_GPIOMUX_INTROUTER0_in_16	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_17	MAIN_GPIOMUX_INTROUTER0_in_17	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse
GPIO0	GPIO0_gpio_18	MAIN_GPIOMUX_INTROUTER0_in_18	MAIN_GPIOMUX_INTROUTER0	GPIO0 interrupt request	pulse

4.9.2 Inter-Integrated Circiuit (I2C)

This section contains the integration details for the I2C module on this device. For further information, see the *Inter-Integrated Circiuit (I2C)* section of the *Peripherals* chapter.

4.9.2.1 I2C Unsupported Features

The following features are not supported on this family of devices:

- Serial Camera Control Bus (SCCB) protocol
- DMA Mode
- Debug suspend mode

The following apply to Main domain instances:

- Full I^2C electrical compliance for I2C modules using device pins with LVCMOS voltage buffers (Refer to chapter 4 of the device-specific Datasheet for details related to device *Terminal Configuration and Functions*)
- High-speed (3.4-Mbps) operation for I2C modules using device pins with LVCMOS voltage buffers (Refer to chapter 4 of the device-specific Datasheet for details related to device *Terminal Configuration and Functions*)
- Asynchronous wakeup (via IO Daisy Chain)

The following apply to MCU domain instances:

- Direct asynchronous wakeup for MCU domain instances

4.9.2.2 I2C Integration

4.9.3 Multichannel Serial Peripheral Interface (MCSPI)

This section contains the integration details for the MCSPI module on this device. For further information, see the *Multichannel Serial Peripheral Interface (MCSPI)* section of the *Peripherals* chapter.

4.9.3.1 MCSPI Unsupported Features

The following features are not supported on this family of devices:

- Peripheral mode wakeup.
- Retention during power down

4.9.3.2 MCSPI Integration

Table 4-284. MCSPI Module Allocations

Instance	MAIN	MCU	WKUP
MCSPI0	✓		
MCSPI1	✓		
MCSPI2	✓

4.9.4 Universal Asynchronous Receiver/Transmitter (UART)

This section contains the integration details for the UART module on this device. For further information, see the *Universal Asynchronous Receiver/Transmitter (UART)* section of the *Peripherals* chapter.

4.9.4.1 UART Unsupported Features

The following features are not supported on this family of devices:

- 12Mbps for MCU and WKUP domains
- Full modem handshaking is not available on all instances. See device Datasheet for instances supporting full modem handshaking.
- Synchronous mode: SCLK is not pinned out
- ISO7816 mode
- SCR DMA mode 2
- Multi-drop transmission
- 9-bit mode

4.10 High-speed Serial Interfaces

4.10.1 Peripheral Component Interconnect Express (PCIe) Subsystem

This section contains the integration details for the PCIe module on this device. For further information, see the *Peripheral Component Interconnect Express (PCIe)* section of the *Peripherals* chapter.

4.10.1.1 PCIE Unsupported Features

The following features are not supported on this family of devices:

- Single Root I/O Virtualization (SR-IOV)
- ATS capability to support virtualization in root port mode
- PCIe beacon for in-band wake
- Vendor Defined Messages (VDM)
- I/O access in inbound direction in RP or EP modes
- Addressing modes other than incremental for burst transactions. Thus, the PCIe addresses cannot be in cacheable memory space.
- L2 power states
- Hot plug

4.10.1.2 PCIe Integration

4.10.2 Gigabit Ethernet Switch (CPSW)

This section contains the integration details for the CPSW module on this device. For further information, see the *Gigabit Ethernet Switch (CPSW)* section of the *Peripherals* chapter.

Copyright © 2026 Texas Instruments Incorporated

4.10.2.1 CPSW Unsupported Features

The following features are not supported on this family of devices:

- Maximum frame size of 9600 bytes
- GMII Mode
- MACSEC
- Synchronous Ethernet

4.10.2.2 cpsw Integration

4.10.3 Universal Serial Bus Subsystem (USB)

This section contains the integration details for the USB module on this device. For further information, see the *Universal Serial Bus 2.0 Subsystem (USB2SS)* and *Universal Serial Bus 3.0 Subsystem (USB3SS)* sections of the *Peripherals* chapter.

4.10.3.1 USB2SS Unsupported Features

The following features are not supported on this family of devices:

- OTG: no Session Request Protocol (SRP) support
- ID pin signaling from USB2 PHY

4.10.3.2 USB3SS Unsupported Features

The following features are not supported on this family of devices:

- Virtualization (SR-IOV, xHCI, or Arm SMMU)
- Direct Debug USB (DDUSB) interface for trace
- Attach Detection Protocol (ADP)
- 5-Volt compatible VBUS pin
- Force event command TRB operating in device mode
- Negotiate Bandwidth command TRB when operating in device mode
- Get Port Bandwidth command TRB when operating in device mode
- Bandwidth request event TRB when operating in device mode
- Doorbell event TRB when operating in device mode
- Device Notification event TRB when operating in device mode
- NRDY event TRB when operating in host mode
- Halt Endpoint command TRB when operating in host mode
- OTG protocol for USB Type-C applications
- Light HC Reset Capability (LHRC)
- xHCI debug capability (Debug Port)
- xHCI save and restore operations
- HIMD when operating in host mode
- Latency tolerance messaging
- Negotiate bandwidth command
- Number of slots limited to 64
- Number of active periodic endpoints limited to 96 when operating in host mode
- Smart ISO
- Secondary streams
- PTM when operating in device mode

4.10.4 Serializer/Deserializer (SerDes)

This section contains the integration details for the SerDes module on this device. For further information, see the *Serializer/Deserializer (SerDes)* section of the *Peripherals* chapter.

4.10.4.1 SerDes Unsupported Features

The following features are not supported on this family of devices:

- SATA over SerDes
- Raw SerDes
- Display Port
- JESD204B

4.10.4.2 SERDES_10G Integration

Table 4-307. SERDES_10G Module Allocations

4.11 Memory Interfaces

4.11.1 Flash Subsystem (FSS)

This section contains the integration details for the Flash Subsystem on this device. For further information, see the *Flash Subsystem (FSS)* section of the *Peripherals* chapter.

4.11.1.1 FSS Unsupported Features

For more information, see Section 4.11.2.1, *OSPI Unsupported Features*.

4.11.1.2 FSS Integration

4.11.2 Octal Serial Peripheral Interface (OSPI)

This section contains the integration details for the OSPI module on this device. For further information, see the *Octal Serial Peripheral Interface (OSPI)* section of the *Peripherals* chapter.

4.11.2.1 OSPI Unsupported Features

The following features are not supported on this family of devices:

- OSPI PDMA. Use CPU-triggered block DMA
- OSPI Clock Phase/Polarity modes 1,2,3
- Reset pins OSPI0_RESET_OUT2, OSPI0_RESET_OUT3

4.11.3 General-Purpose Memory Controller (GPMC)

This section contains the integration details for the GPMC module on this device. For further information, see the *General-Purpose Memory Controller (GPMC)* section of the *Peripherals* chapter.

4.11.3.1 GPMC Unsupported Features

The following features are not supported on this family of devices:

- Pins GPMC_CS[7:4]n are not pinned out
- Pins GPMC_A[27:23] are not pinned out
- Pins GPMC_AD[31:16] are not pinned out
- Pins GPMC_WAIT[3:2] are not pinned out
- Pins GPMC_BE[3:2]n are not pinned out

4.11.3.2 GPMC Integration

4.11.5 Multimedia Card Secure Digital (MMCSD)

This section contains the integration details for the MMCSD module on this device. For further information, see the *Multimedia Card Secure Digital (MMCSD)* section of the *Peripherals* chapter.

4.11.5.1 MMCSD Unsupported Features

The following features are not supported on this family of devices:

- The following apply to 4-bit MMCSD instances:
  - SD Card busy LED: Not pinned out
- The following apply to 8-bit MMCSD instances:
  - SD Card busy LED - Not pinned out
  - SD/SDIO/MMC Cards (Removable) - no support for 4-pin/8-pin muxing
  - SD Card Detect Pin - Not pinned out
  - SD Card Write Protect Pin - Not pinned out
  - Enhanced Strobe
  - IO retention
  - Muxing of LVCMOS functions with the PHY at the SoC level

4.11.5.2 MMCSD4 Integration

Table 4-327. MMCSD4 Module Allocations

Instance	MAIN	MCU	WKUP

4.12 Industrial and Control Interfaces

4.12.1 Modular Controller Area Network (MCAN)

This section contains the integration details for the MCAN module on this device. For further information, see the *Modular Controller Area Network (MCAN)* section of the *Peripherals* chapter.

4.12.1.1 MCAN Unsupported Features

The following features are not supported on this family of devices:

- Debug DMAs: DMA Ack is not supported by PDMA architecture. Debug messages can be traced through the RX FIFO.
- TX DMA channels 3-31 are not supported by the Main domain instance/s. Only TX_DMA[2:0] have associated PDMA channels.
- DMA is not supported by the MCU domain instance/s

4.12.1.2 MCAN Integration

4.12.3 Enhanced Pulse Width Modulation (EPWM)

This section contains the integration details for the EPWM module on this device. For further information, see the *Enhanced Pulse Width Modulation (EPWM)* section of the *Peripherals* chapter.

4.12.3.1 EPWM Unsupported Features

The following features are not supported on this family of devices:

- EPWM digital comparators
- High resolution extension (delay-line based)

4.12.3.2 EPWM Integration

Table 4-347. EPWM Module Allocations

Instance	MAIN	MCU	WKUP
EPWM0	✓		
EPWM1	✓		
EPWM2	✓		

Table 4-348. Integration Attributes for EPWM

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
EPWM0	PSC0	GP_CORE	LPSC_main_ip	34	ON	YES	LPSC_main_dm2main_infra_iso
EPWM1	PSC0	GP_CORE	LPSC_main_ip	34	ON	YES	LPSC_main_dm2main_infra_iso
EPWM2	PSC0	GP_CORE	LPSC_main_ip	34	ON	YES	LPSC_main_dm2main_infra_iso

Table 4-349. Clock Integration for EPWM

Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
EPWM0	FICLK	MAIN_SYSCLK0/2		functional and interface clock
EPWM1	FICLK	MAIN_SYSCLK0/2		functional and interface clock
EPWM2	FICLK	MAIN_SYSCLK0/2		functional and interface clock

Table 4-350. Reset Integration for EPWM

Module Instance	Source	Description
EPWM0	PSC0	EPWM0 reset
EPWM1	PSC0	EPWM1 reset
EPWM2	PSC0	EPWM2 reset

Table 4-351. Hardware Requests for EPWM

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type

4.12.4 Enhanced Quadrature Encoder Pulse (EQEP)

This section contains the integration details for the EQEP module on this device. For further information, see the *Enhanced Quadrature Encoder Pulse (EQEP)* section of the *Peripherals* chapter.

4.12.4.1 EQEP Unsupported Features

The following features are not supported on this family of devices:

- EQEPA_i[15:1], EQEPB_i[15:1] are not pinned out.

4.12.4.2 EQEP Integration

Table 4-352. EQEP Module Allocations

Instance	MAIN	MCU	WKUP
EQEP0	✓		
EQEP1	✓		
EQEP2	✓		

Table 4-353. Integration Attributes for EQEP

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
EQEP0	PSC0	GP_CORE	LPSC_main_ip	34	ON	YES	LPSC_main_dm2main_infra_iso
EQEP1	PSC0	GP_CORE	LPSC_main_ip	34	ON	YES	LPSC_main_dm2main_infra_iso
EQEP2	PSC0	GP_CORE	LPSC_main_ip	34	ON	YES	LPSC_main_dm2main_infra_iso

Table 4-354. Clock Integration for EQEP

Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
EQEP0	FICLK	MAIN_SYSCLK0/4		functional and interface clock
EQEP1	FICLK	MAIN_SYSCLK0/4		functional and interface clock
EQEP2	FICLK	MAIN_SYSCLK0/4		functional and interface clock

Table 4-355. Reset Integration for EQEP

Module Instance	Source	Description
EQEP0	PSC0	EQEP0 reset

4.13 Camera Subsystem

4.13.1 Camera Serial Interface Receiver (CSI_RX_IF)

This section contains the integration details for the CSI_RX_IF module on this device. For further information, see the *Camera Serial Interface Receiver (CSI_RX_IF)* section of the *Peripherals* chapter.

4.13.1.1 CSI_RX_IF Unsupported Features

The following features are not supported on this family of devices:

- Line Count Error interrupt (Streams 1-3)
- Frame Mismatch Error interrupt (Streams 1-3)
- Frame Count Error interrupt (Streams 1-3)
- FCC Stop interrupt (Streams 1-3)
- FCC Start interrupt (Streams 1-3)
- Line/Byte interrupt (Streams 1-3)
- Timer / Timer interrupt (Streams 1-3)

4.13.1.2 csi_rx_if Integration

Table 4-357. CSI_RX_IF Module Allocations

Instance	MAIN	MCU	WKUP
csi_rx_if0	✓		
csi_rx_if1	✓		
csi_rx_if2	✓		
csi_rx_if3	✓		

Table 4-358. Integration Attributes for csi_rx_if

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
csi_rx_if0	PSC0	GP_CORE	LPSC_main_csi_rx0	25	OFF	YES	LPSC_main_dphy_rx0
csi_rx_if1	PSC0	GP_CORE	LPSC_main_csi_rx1	9	OFF	YES	LPSC_main_dphy_rx1
csi_rx_if2	PSC0	GP_CORE	LPSC_main_csi_rx2	48	OFF	YES	LPSC_main_csi_dphy_rx2
csi_rx_if3	PSC0	GP_CORE	LPSC_main_csi_rx3	44	OFF	YES	LPSC_main_dphy_rx3

Table 4-359. Clock Integration for csi_rx_if

Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
csi_rx_if0	CSI_RX_MAIN_CLK	MAIN_SYSCLK0		main_clk clock runs the csi2 core and psil dma.
csi_rx_if0	CSI_RX_BYTE_CLK	DPHY_RX0 (INSTANCE)		byte_clk is the clock supplied by the dphy_rx pll and is divided down to byte clock. the dphy_rx is designed for max of 10gbps. this translates to a max byte clock of 312.5mhz. the clock is inactive when dphy_rx is not in hs operation
csi_rx_if0	CSI_RX_VBUS_CLK	MAIN_SYSCLK0/2		interface configuration clock that runs at half the speed of the main_clk
csi_rx_if0	CSI_RX_VP_CLK	MAIN_PLL5_HSDIV0_CLKOUT		video port clock
csi_rx_if1	CSI_RX_MAIN_CLK	MAIN_SYSCLK0		main_clk clock runs the csi2 core and psil dma.

4.13.2 MIPI D-PHY Receiver (DPHY_RX)

This section contains the integration details for the DPHY_RX module on this device. For further information, see the *MIPI D-PHY Receiver (DPHY_RX)* section of the *Peripherals* chapter.

4.13.2.1 DPHY_RX Unsupported Features

The following features are not supported on this family of devices:

- Swapping of clock and data lanes

4.13.2.2 dphy_rx Integration

4.14.2 Real Time Interrupt (RTI)

This section contains the integration details for the RTI module on this device. For further information, see the *Real Time Interrupt (RTI)* section of the *Peripherals* chapter.

4.14.2.1 RTI Not Supported Features

The following features are not supported on this family of devices:

- Analog watchdog timer
- External clock supervision
- Periodic interrupt
- Timestamp (Capture registers)

Note

The integration only supports one feature - use of the RTI as a Digital Windowed Watchdog. All other features (captures, compares, interrupts, network time unit) are not supported.

Note

The domain instances of the RTI module are intended to function as a Digital Windowed Watchdog for the CPU core that they are associated with (by instance name).

4.14.2.2 RTI Integration

Table 4-376. RTI Module Allocations

4.14.3 Real-Time Clock (RTC)

This section contains the integration details for the RTC module on this device. For further information, see the *Real-Time Clock (RTC)* section of the *Peripherals* chapter.

4.14.3.1 RTC Unsupported Features

The following features are not supported on this family of devices:

- PMIC enable support
- Analog IP support
- External IO
- Two digital voltage domains

4.14.3.2 rtcss Integration

4.14.4 Timer

This section contains the integration details for the Timer module on this device. For further information, see the *Timer* section of the *Peripherals* chapter.

4.14.4.1 Timer Unsupported Features

The following features are not supported on this family of devices:

- Cascading of timer instances

4.14.4.2 TIMER Integration

4.15 Internal Diagnostic Modules

4.15.1 Dual Clock Comparator (DCC)

This section contains the integration details for the DCC module on this device. For further information, see the *Dual Clock Comparator (DCC)* section of the *Peripherals* chapter.

4.15.1.1 DCC Integration

Table 4-392. DCC Module Allocations

Instance	MAIN	MCU	WKUP
DCC0	✓

4.15.2 Error Signaling Module (ESM)

This section contains the integration details for the ESM module on this device. For further information, see the *Error Signaling Module (ESM)* section of the *Peripherals* chapter.

4.15.2.1 ESM Unsupported Features

The following features are not supported on this family of devices:

- No Dedicated ERROR Pin for MAIN domain ESM. MAIN ESM error interrupts are routed to the MCU ESM - the MCU ESM drives the MCU_ERROR pin and can factor in errors from MAIN ESM if programmed to do so.

4.15.2.2 ESM Integration

Table 4-408. ESM Module Allocations

Instance	MAIN	MCU	WKUP
WKUP_ESM0			✓
ESM0	✓		

Table 4-409. Integration Attributes for ESM

Module Instance	Power Sleep Controller	Power Domain	Module Domain	Index	Default	Controllable	Dependencies
WKUP_ESM0	WKUP_PSC0	GP_core_CTL_MCU	LPSC_mcu_alwayson	0	ON	NO	
ESM0	PSC0	GP_CORE	LPSC_main_alwayson	0	ON	NO	

Table 4-410. Clock Integration for ESM

Module Instance	Module Clock Input	Source Clock	Source Control Register	Description
WKUP_ESM0	FICLK	MCU_SYSCLK0/4		functional and interface clock
ESM0	CLK	MAIN_SYSCLK0/4		None

Table 4-411. Reset Integration for ESM

Module Instance	Source	Description
WKUP_ESM0	WKUP_PSC0	WKUP_ESM0 reset
ESM0	PSC0	ESM0 reset

Table 4-412. Hardware Requests for ESM

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type

4.15.3 Memory Cyclic Redundancy Check (MCRC64)

This section contains the integration details for the MCRC64 module on this device. For further information, see the *Memory Cyclic Redundancy Check (MCRC)* section of the *Peripherals* chapter.

4.15.3.1 MCRC64 Unsupported Features

The following features are not supported on this family of devices:

- Data Trace Mode (Automatic PSA on CPU Instruction and Data TCM busses) - Wrapper only supports VBUSM Signature Analysis. ITCM, DTCM designed for Cortex R5F
- DMA is not supported by the MCU instances

4.15.3.2 MCRC64 Integration

Table 4-413. MCRC64 Module Allocations

Instance	MAIN	MCU	WKUP
MCRC64_0	✓		
MCU_MCRC64_0		✓

Chapter 5

Initialization

This chapter describes the steps for non-secure device initialization.

5.1 Initialization Overview 353
5.2 Boot Process 356
5.3 Boot Mode Pins 361
5.4 Boot Modes 363
5.5 PLL Configuration 393
5.6 Boot Parameter Tables 395
5.7 Boot Image Format 405
5.8 Boot Memory Maps 412

Copyright © 2026 Texas Instruments Incorporated

5.1 Initialization Overview

Figure 5-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power, clock, reset ramp sequence:** Specific sequence that is applied by the power-management chip(s)
- **ROM code:** Responsible for finding, for downloading, and for executing the initial software (SBL)
- **Initial software:** Software that loads, prepares, and passes control to application software or to the high-level operating system (HLOS)
- **High-Level Operating System** or bare-metal application which runs on main processor(s)

Figure 5-1. Initialization Process

The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins, the associated configuration registers, and memory structures that are vital to the correct initialization of the device.

5.1.1 ROM Code Overview

ROM bootloader (or ROM Code) is a software that resides in a on-chip read-only memory (ROM) to assist the customer in transferring and executing their application code. The device has two ROM codes operating in tandem – the Public ROM code, and the M4 ROM code.

In order to accommodate various system scenarios, the ROM Code supports several boot modes. These boot modes can be broadly classified as:

- Host boot modes
- Memory boot modes.

During a host boot, the device is configured to receive code from a host via the selected interface. Either the host writes the application code directly into internal memory or the ROM Code receives the application code on the selected interface and stores it in internal memory.

During a memory boot, the device transfers code from non-volatile memory to internal memory for execution.

In all boot modes, the entire boot operation can be partitioned into two sections:

1. Hardware initialization phase
2. Boot process.

During initialization, the ROM Code configures the device resources (PLLs, peripherals, pins) as needed to support the boot process. The resources used depend on the boot mode requirements.

During the boot process the boot image can be loaded into device memory and executed, or executed in place, depending on the boot peripheral. M4 will perform code verification and allow, or forbid, the image execution.

Main configuration source for boot after power-up are the BOOTMODE pins sampled automatically after reset release and stored in device status registers. At ROM Code startup, these pin values are read from the registers to create the boot peripheral list and the boot configuration tables used later to initialize and startup the PLLs and boot peripherals.

5.1.2 Bootloader Modes

Table 5-1 shows the boot modes supported by ROM code.

Table 5-1. ROM Code Boot Modes

Boot Mode	Boot Media/Host	SoC Peripheral	Can be a Backup Mode?(1)	Notes
No-boot/Dev-boot	No media or host	None	N	No boot or development boot – debug modes
OSPI	OSPI flash	FSS0_OSPI0	N	On OSPI port
QSPI	QSPI flash	FSS0_OSPI0	N	On OSPI port
SPI	SPI flash	FSS0_OSPI0	Y	On OSPI port
Ethernet	External host	CPSW0	Y	In BOOTP mode. RGMII or RMII PHY
I2C	I^2C EEPROM	I2C0	Y	I2C target boot is not supported
UART	External host	UART0	Y	XMODEM protocol
MMCSD	MMCSD card	MMCSD0 (8bit) or MMCSD1 (4bit)	Y	Boot from User Data Area (UDA) or file system
eMMC	eMMC flash	MMCSD0 (8bit)	N	Boot from boot partition
USB - target	USB boot from external host	USB0	Y	USB device mode boot using DFU (device firmware upgrade), Boot is running on USB2.0 speeds.
USB - host	USB mass storage	USB0	Y	USB2.0 host mode, boot from FAT32 filesystem
Serial Flash	Serial Flash	FSS0_OSPI0	N	On OSPI port
xSPI	xSPI flash	FSS0_OSPI0	N	On OSPI port
Fast-xSPI	Fast-xSPI	FSS0_OSPI0	N	On OSPI port
GPMC	NOR flash, NAND flash	GPMC0	N	CSn0 connected, 8 bit NAND flash only, 16-bit non-mux NOR flash only

(1) The peripheral can be selected also as a backup boot mode. A backup mode is tried if primary boot mode fails.

Note

Because different devices support different sets of peripherals, see the *device-specific Datasheet* to obtain the list of peripherals supported in your device.

5.1.3 Terminology

- **Boot Mode Pins:** Boot mode pins provide vital information to ROM code for boot. These pins must be properly set up before power ramp.
- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase.
- **Boot Header:** Optional structure that precedes the initial software and allows the redefinition of the ROM code default settings.
- **Downloaded software:** Initial software downloaded into on-chip RAM by the ROM code during the peripheral booting phase.
- **eFuse:** A one-time programmable memory location usually set at the factory.
- **Flash loader:** Downloaded software launched by the ROM code during the preflashing stage. It also programs an image in external memories.
- **GP device:** General-purpose device (SoC) or a non-secure device.
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software. This can be the SBL (secondary bootloader) responsible for loading an OS.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory.

Copyright © 2026 Texas Instruments Incorporated

- **Controller CPU:** The Arm® Cortex® CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory.
- **ROM Code:** or ROM bootloader (RBL), the on-chip software in device ROM that executes first and implements booting.
- **ROM Code-controlled Boot Phase:** This phase covers the sequence operations from the time the platform releases the reset to the time first user- or customer-owned software starts execution. This phase is fully controlled by the device ROM code.
- **Booting Parameter Table:** A logical structure stored in the on-chip RAM memory and contains information for the boot, such as the boot file name or an address to boot from.

5.2 Boot Process

5.2.1 Public ROM Code Architecture

The Public ROM code has the following components (see also Public ROM Code Architecture):

- Main
- Buffer manager
- X.509
- Log and Trace
- System
- Protocol
- Driver

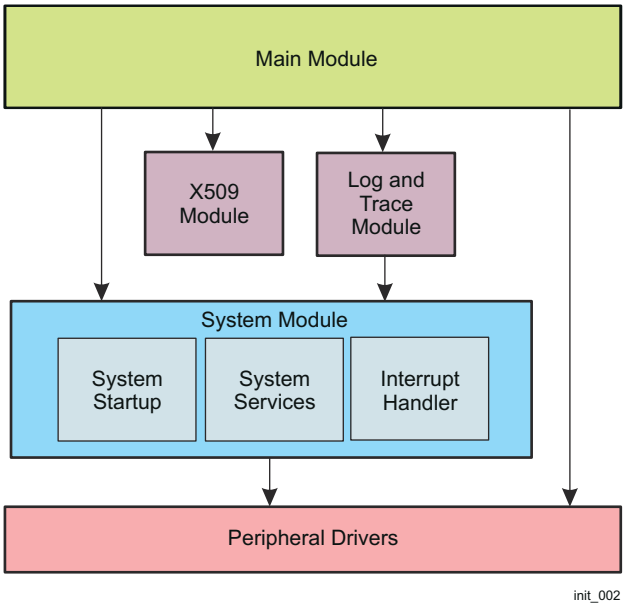

Figure 5-2. Public ROM Code Architecture

5.2.1.1 Main Module

The Main module contains the top level execution loop. This loop repeats until a boot image has been received or directed to sleep by the M4. The main loop has three different execution sub-paths based on the boot peripheral.

- **Image Path** This path is used by the OSPI, QSPI, SPI, and xSPI boot modes. In these cases the image data can be directly read by both the R5 and the M4 in place.
- **Block Path** This path is used by the I2C, USB-DFU, UART, eMMC, Ethernet, eMMC/SD cards in raw mode. In this mode data is received from the peripheral in blocks. Blocks are accumulated in the boot buffer until a full X.509 certificate header has been received, at which point this full certificate and any subsequent blocks are passed to the M4 as they arrive.
- **Filesystem Path** This path is used by the USB host (MSC) mode and eMMC/SD cards in filesystem mode. This mode executes exactly like in the block path, except that the boot image location is defined by a filesystem.

The main level is able to detect if a received boot image is in the correct format and reject non-conforming images. In some cases, detection of an invalid image is done after the initial data buffer has been sent to the M4. In that case the R5 must inform the M4 that the image was in fact invalid and it will be looking for the next image and try again.

Copyright © 2026 Texas Instruments Incorporated

5.2.1.2 X509 Module

The X509 module parses the boot header. The boot header is an X.509 certificate as defined in RFC5280. Extensions specific to boot are described in Section 5.7.2, *X.509 Certificate*.

This module also includes an OID decoder as well as defines OID values as C #define constants for any values that can be used during boot.

5.2.1.3 Buffer Manager Module

The buffer manager module is used to allocate buffers to hold boot data. The R5 code allocates a buffer when it is ready to read a block of data from the boot peripheral. Once the data is read the buffer ownership is passed to the M4. When the M4 has completed processing the data in the buffer ownership is returned to the R5, which then frees the buffer.

5.2.1.4 Log and Trace Module

The Log and Trace modules are not integral to the boot process. Instead, they provide ability to record operation of the ROM code and track unexpected occurrences.

Log and trace function is currently TI internal.

5.2.1.5 System Module

The system module provides services to other modules. These services are not directly related to boot drivers. The system module is the only module that operates in the supervisor mode of the R5 (a few services will run in user). The system module supports the following functions:

- Interrupt enable, disable, and service
- IPC
- Power
- Pinmux
- Clock
- Task switch

The main level is able to detect if a received boot image is in the correct format and reject non-conforming images.

5.2.1.6 Protocol Module

The protocol modules provide implementation of high-level data transfer protocols. The BOOTP/TFTP and XMODEM protocols reside in this layer. These modules provide services as defined in well-known standards.

5.2.1.7 Driver Module

The driver module implements the low level peripheral drivers.

5.2.2 M4 ROM Description

In a general-purpose (GP) device, M4 ROM performs the following functions:

- Device management
- Configures the boot vectors (in BOOT_CFG) and controls reset release of R5 core. That is, M4 is the boot controller of R5 core.
- IPC configuration via Main DMSS rings and Secure Proxy
- PLL configuration (R5 and SA2UL)
- X509 certificate parsing
- SA2UL configuration to SHA512 for image integrity checks
- M4 firmware loading

5.2.3 Boot Process Flow

The R5 boot process flow is shown in Figure 5-3.

Copyright © 2026 Texas Instruments Incorporated

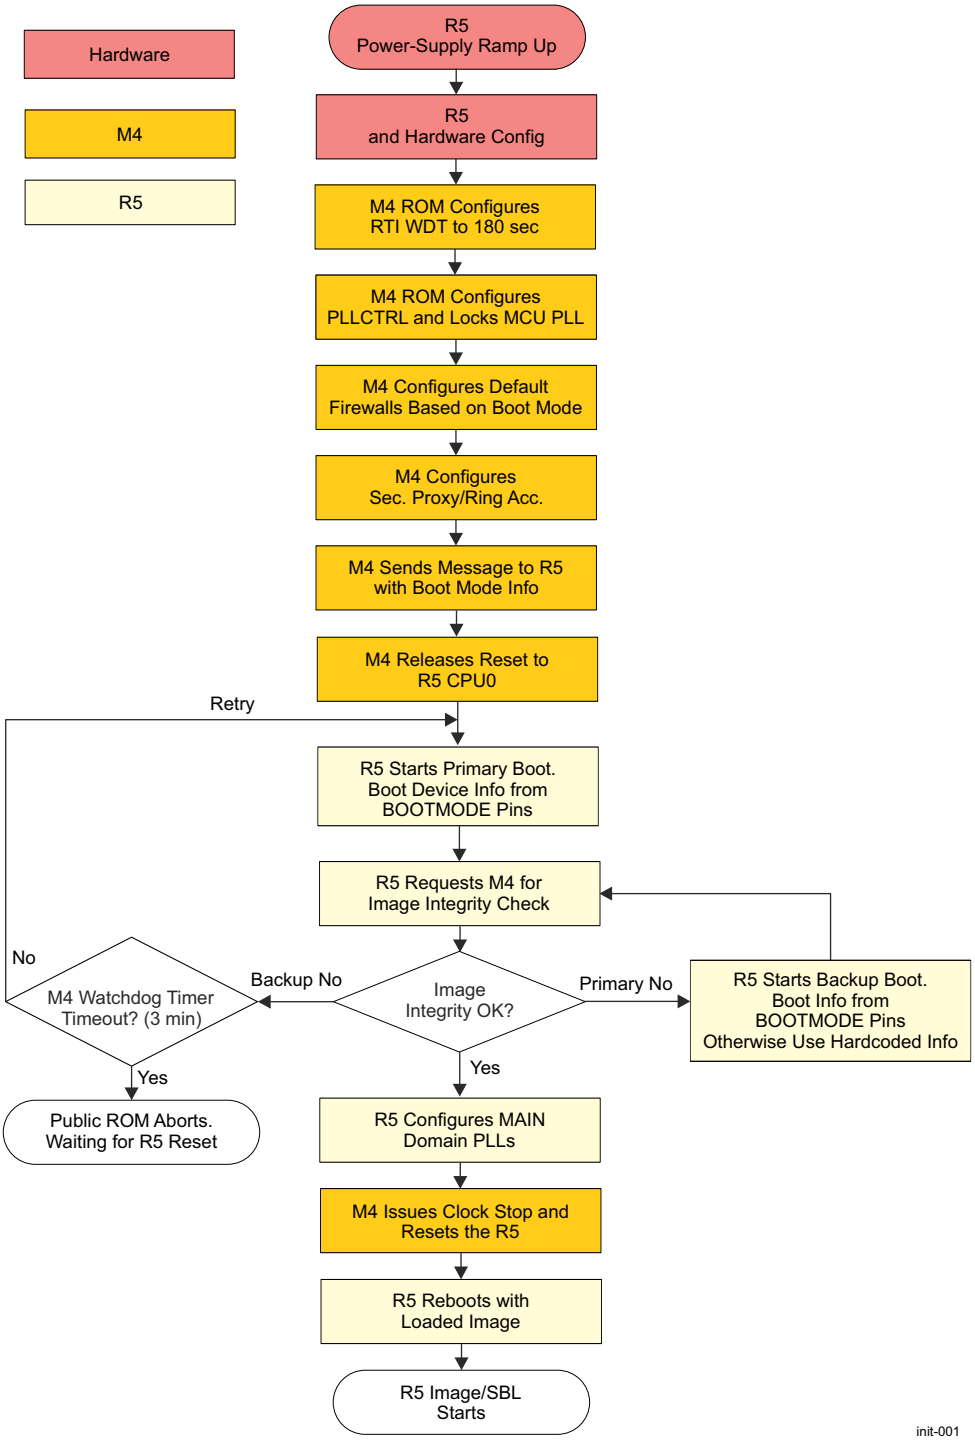

Figure 5-3. Boot Process

The values of BOOTMODE[15:0] pins are latched into the Device Status register CTRLMMR_MAIN_DEVSTAT[15:0] by hardware as the device comes out of global cold reset, sampled after MCU_PORz deassertion. For more information how to set BOOTMODE pins, see Section 5.3, *Boot Mode Pins*.

The M4 is the boot controller for the Public ROM. M4 performs the necessary configurations and releases R5's reset for CPU0.

Copyright © 2026 Texas Instruments Incorporated

The R5 checks the boot mode pins and then configures the apropriate peripheral interface to get access to a boot image. A cursory check of the image is made, and the image is passed to M4. M4 ROM then will perform code verification and route the boot image to the on-chip RAM. Once the image has been received, R5 enters a clean state and idles. M4 ROM code will assert reset to the R5, redirect the boot vector to the newly loaded image, and release the reset. This restarts the R5 with the Public ROM code fully disconnected.

The Public ROM code executes after a cold or warm reset.

Note

M4 ROM sets up a 3-minute watchdog timer (RTI0) timeout. During this time, the R5 boot needs to get completed, otherwise a WDT reset will occur. Once the R5 image is loaded (SBL/SPL), M4 ROM will restart the watchdog timer for additional 3 minutes upon entering the R5 SBL. The customer-provided R5 image needs to load and install the TI-provided SYSFW image into the M4, which will manage the watchdog timer during run time.

Note

The following system conditions must be met at POR to perform device boot:

- USB cable plug must be inserted
- Ethernet PHY is powered up and out of reset
- The SD card cage must be powered before entering the SD card boot mode. A SD/MMC card with pre-loaded image must be inserted
- Memory devices must be up and ready (power ramped up and reset completed) at device startup:
  - eMMC
  - xSPI/OSPI/QSPI/SPI and Serial flash
  - I2C EEPROM
  - NOR/NAND flash

Failing to meet these requirements may result in boot fail and performing a backup boot (if available for that mode).

Figure 5-4 describes the external bootloader (SBL) typical tasks.

Copyright © 2026 Texas Instruments Incorporated

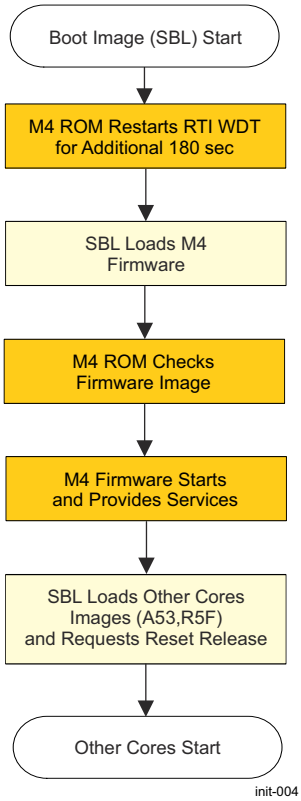

Figure 5-4. External Bootloader Tasks

Upon R5 reset and SBL execution start, M4 ROM restarts the RTI watchdog timer for additional 180 seconds of timeout. During that time, SBL must load the M4 firmware provided by TI otherwise an R5 reset will occur as a preventive measure against software misbehavior.

One of the SBL's main tasks is to load the M4 firmware. Only after this task is performed, SBL can load the other processors' image and request a reset release from M4 firmware for those cores.

Copyright © 2026 Texas Instruments Incorporated

5.3 Boot Mode Pins

Boot Mode pins provide means to select the boot mode and options before the device is powered up. After every POR, they are the main source to populate the Boot Parameter Tables. See Section 5.6, *Boot Parameter Tables* for table list and description.

Boot mode pins can be divided into the following categories:

- **BOOTMODE[02:00]** – Denote system clock frequency (MCU_OSC0_XI/XO) to ROM code for PLL configuration.
- **BOOTMODE[06:03]** – Select the requested boot (primary) mode after POR, that is, the peripheral/memory to boot from.
- **BOOTMODE[09:07]** – These pins provide optional configurations for primary boot and are used in conjunction with the boot mode selected.
- **BOOTMODE[12:10]** – Select the backup boot mode, that is, the peripheral/memory to boot from, if primary boot device failed.
- **BOOTMODE[13]** – This pin provides optional configurations for the backup boot devices.
- **BOOTMODE[15:14]** – Reserved pins.

Note

It is user's responsibility to set the boot mode pins (via pullups or pulldowns, and jumpers/switches) depending on the desired boot scenario.

Copyright © 2026 Texas Instruments Incorporated

5.3.1 BOOTMODE Pin Mapping

The ROM execution is directed through the main boot mode pins. This provides more flexibility and more booting peripherals to boot from. The Main domain must be powered and functional.

Main boot mode pins are shown in Table 5-2.

Table 5-2. BOOTMODE Pin Mapping

B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
0	0	Backup Boot Mode Config	Backup Boot Mode			Primary Boot Mode Config			Primary Boot Mode				PLL Config		

Table 5-3 describes the BOOTMODE pins that need to be set according to the system clock provided to the device.

The ROM Code will configure any PLLs required during the boot process.

Note

Reference clock selections may be limited by the device. Please consult the device specific Datasheet to determine which system clock frequencies are valid.

Table 5-3. PLL Reference Clock Selection

PLL Config Pins			Ref Clock (MHz)
B2	B1	B0	
0	1	0	Reserved
0	1	1	25
1	0	0	Reserved

5.3.1.1 Primary Boot Mode Selection and Configuration

The primary boot mode is the first mode attempted after reset. Table 5-4 lists all possible primary boot modes.

Note

All BOOTMODE[15:00] signals must be pulled high through a resistor to VDDSHV3, or pulled low to ground, including Reserved signals. Reserved BOOTMODE signals are recommended to be pulled low.

Table 5-4. Primary Boot Mode Selection

Primary Boot Mode Config							Primary Boot Mode
B9	B8	B7	B6	B5	B4	B3

Reserved	1	1	0	SPI
Reserved	1	1	1	I2C

5.4 Boot Modes

Copyright © 2026 Texas Instruments Incorporated

5.4.1 Boot with OSPI Controller

The following apply to all or multiple boot modes that are SPI related.

- Octal SPI flash memories support various protocols, however, the OSPI boot mode of the device will only support a specific protocol defined in OSPI Bootloader Operation. If the flash memory is complaint with JEDEC xSPI standards JESD251 and JESD216D, then xSPI boot mode is additionally supported. Please refer to xSPI boot mode description for further details.
- Command protocols follow the JEDEC spec definition and indicate the number of active pins used for the instruction, address, and data, and also the data rate used for each (S = Single Data Rate, D= Double Data Rate). For example, 1S-1S-8S describes a protocol which uses 1 signal (D0) for command in SDR mode, 1 signal (D0) for address in SDR mode, and 8 signals (D7:D0) for data in SDR mode
- When using a OSPI\xSPI\QSPI\SPI flash device greater than 128Mb which supports 3-byte and 4-byte addressing modes, a flash device package with a RESET signal must be used. The reason is that the ROM only uses 3 byte addressing mode (address is 24bits). To address the full memory address range, software will typically switch to 4-byte addressing mode. If a reset to the processor occurs (eg, due to a warm reset), the ROM will execute expecting 3-byte addressing mode, but the flash will have been left in 4-byte addressing mode. In order for the flash device to return to 3-byte addressing mode, it must be reset using this signal. This typically can be achieved by using the RESET signal on the flash memory device. The ROM does not issue a software reset command.

5.4.1.1 OSPI Boot

Table 5-6 shows configuration pins assignment to functions when boot mode is the Octal SPI using the OSPI module.

Table 5-6. OSPI Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
7	Csel	0	Boot Flash is on CS 0
		1	Boot Flash is on CS 1

Table 5-7 summarizes the OSPI pin configuration done by ROM code for OSPI boot device.

Table 5-7. OSPI Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_D4	OSPI0_D4	Disable	NA	0	Enable	0	PADCONFIG7
OSPI0_D5	OSPI0_D5	Disable	NA	0	Enable	0	PADCONFIG8
OSPI0_D6	OSPI0_D6	Disable	NA	0	Enable	0	PADCONFIG9
OSPI0_D7	OSPI0_D7	Disable	NA	0	Enable	0	PADCONFIG10
OSPI0_CSn0(1)	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1(1)	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

(1) OSPI0_CSn0 and OSPI0_CSn1 are configured as chip select outputs from the OSPI0 host controller, but OSPI boot only uses the chip select output selected via BOOTMODE[7].

Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.1.1.1 OSPI Bootloader Operation

Please refer to Section 5.4.1 for more information that applies to OSPI boot mode

The OSPI boot mode supports 1S-1S-8S mode only. The ROM will issue a Read Command (0x8B) followed by a 24 bit (3 byte) address (the starting address is all zeros), followed by 8 dummy cycles. The flash device should then respond with 8-bit data. The frequency of operation during the read portion is 50 MHz.

5.4.1.1.1.1 OSPI Initialization Process

In the OSPI boot mode, the ROM Code initializes the OSPI module and the image is read from the OSPI flash connected to the selected chip-select. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM. See Section 5.4.1.1, *OSPI Boot Device Configuration* for OSPI port settings.

A detailed summary of the OSPI boot parameter table and the boot configuration definitions are listed in Section 5.6.3, *OSPI Boot Parameter Table*.

5.4.1.1.1.2 OSPI Loading Process

OSPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

Copyright © 2026 Texas Instruments Incorporated

5.4.1.2 xSPI Boot

Table 5-8 shows configuration pins assignment to functions when boot mode is xSPI using the OSPI module.

Table 5-8. xSPI Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
9	SFDP	0	SFDP disabled
		1	SFDP enabled
8	Read cmd	0	0x0B Read Command
		1	0xEE Read Command
7	Mode	0	1S-1S-1S mode @ 50MHz
		1	8D-8D-8D mode @ 25MHz

Table 5-9 summarizes the OSPI pin configuration done by ROM code for xSPI boot device on port 0.

Table 5-9. xSPI Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_D4	OSPI0_D4	Disable	NA	0	Enable	0	PADCONFIG7
OSPI0_D5	OSPI0_D5	Disable	NA	0	Enable	0	PADCONFIG8
OSPI0_D6	OSPI0_D6	Disable	NA	0	Enable	0	PADCONFIG9
OSPI0_D7	OSPI0_D7	Disable	NA	0	Enable	0	PADCONFIG10
OSPI0_CSn0(1)	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1(1)	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

(1) Both OSPI0_CSn0 and OSPI0_CSn1 are configured as chip select outputs from the OSPI0 host controller, but xSPI boot only uses OSPI0_CSn0. It is not possible to select OSPI0_CSn1 as a chip select option for xSPI boot.

Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.1.2.1 xSPI Bootloader Operation

Please refer to Section 5.4.1 for more information that applies to xSPI boot mode

The xSPI protocol defines 1S-1S-1S mode for general backwards compatibility, and 8D-8D-8D for maximum throughput.

For 1S-1S-1S mode of operation, the ROM will issue a Fast Read Output command (0x0B) followed by a 24 bit (3 byte) address (the starting address is all zeros), followed by 8 dummy cycles. The frequency of operation is 50 MHz.

For 8D-8D-8D mode of operation, the ROM will issue a Fast Read command (0x0B or 0xEE, depending on BOOTMODE signal), followed by a 32 bit (4 byte) address (the starting address is all zeros). The frequency of operation is 25 MHz.

When SFDP is enabled using a BOOTMODE signal, the ROM starts operation in 1S-1S-1S mode reads SFDP header from flash memory to get 8D-8D-8D switching sequence, Read Command, CMD Extension and Byte

Copyright © 2026 Texas Instruments Incorporated

Order. SFDP parsing of ROM is described below and on successful parsing ROM will issue 8D-8D-8D command switching sequence and then will read the boot image in 8D-8D-8D mode with read command specified in SFDP header

Copyright © 2026 Texas Instruments Incorporated

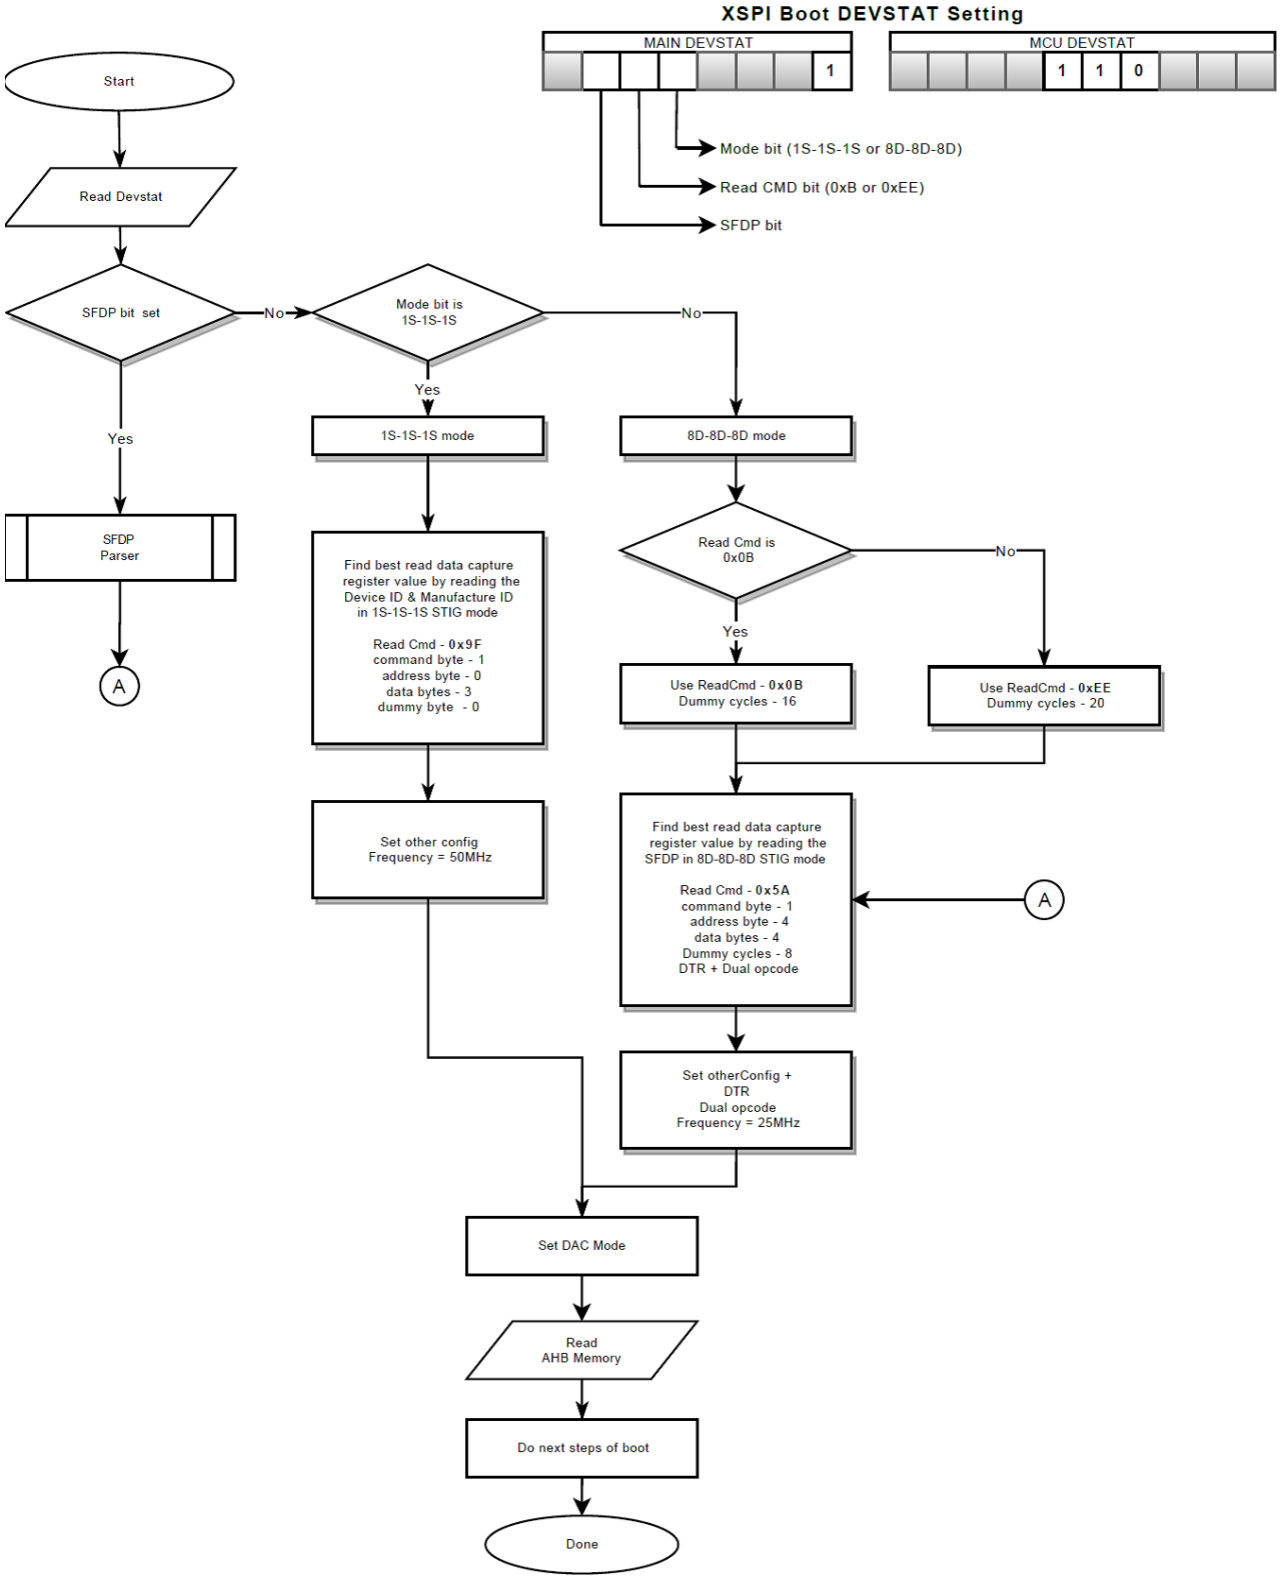

Figure 5-5. xSPI Flow Chart

Copyright © 2026 Texas Instruments Incorporated

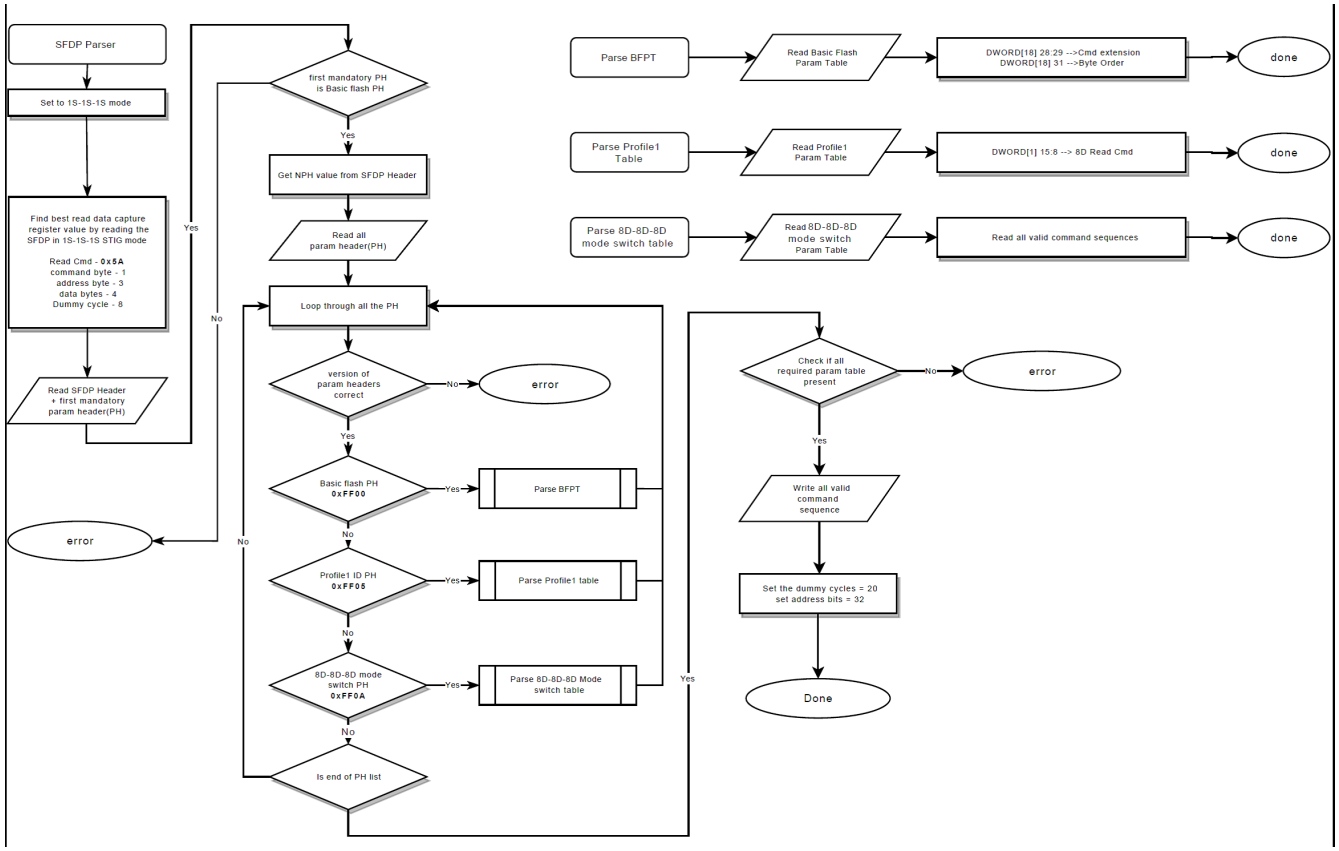

Figure 5-6. ROM SFDP Parser Flow

5.4.1.3 Fast-xSPI Boot Mode Configuration

The Fast-xSPI boot mode is an extension of the xSPI boot mode where the OSPI PHY will be tuned in order to set the frequency of operation to 100MHz for 8D-8D-8D mode. Flash needs to support SFDP.

To support Fast-xSPI boot, ROM expects the tuning configuration in the last sector of flash which is determined by the flash device configuration. Absence of the configuration will cause ROM to switch the non-PHY based/ standard xSPI boot.

ROM will get the flash memory density (flash memory size **S**) andlargest erase sector size (**E** bytes) from the BFPT table and calculates the beginning of last sector as E bytes from the end of flash. We call this location as start of the configuration data (**C0 = S - E**)

Supported Configurations:

1. ROM will support online PHY tuning as specified by the search bounds in the configuration data
2. ROM will support offline PHY tuning as specified by the delays in the configuration data

Selection between the two configurations is through magic words defined by ROM.

Copyright © 2026 Texas Instruments Incorporated

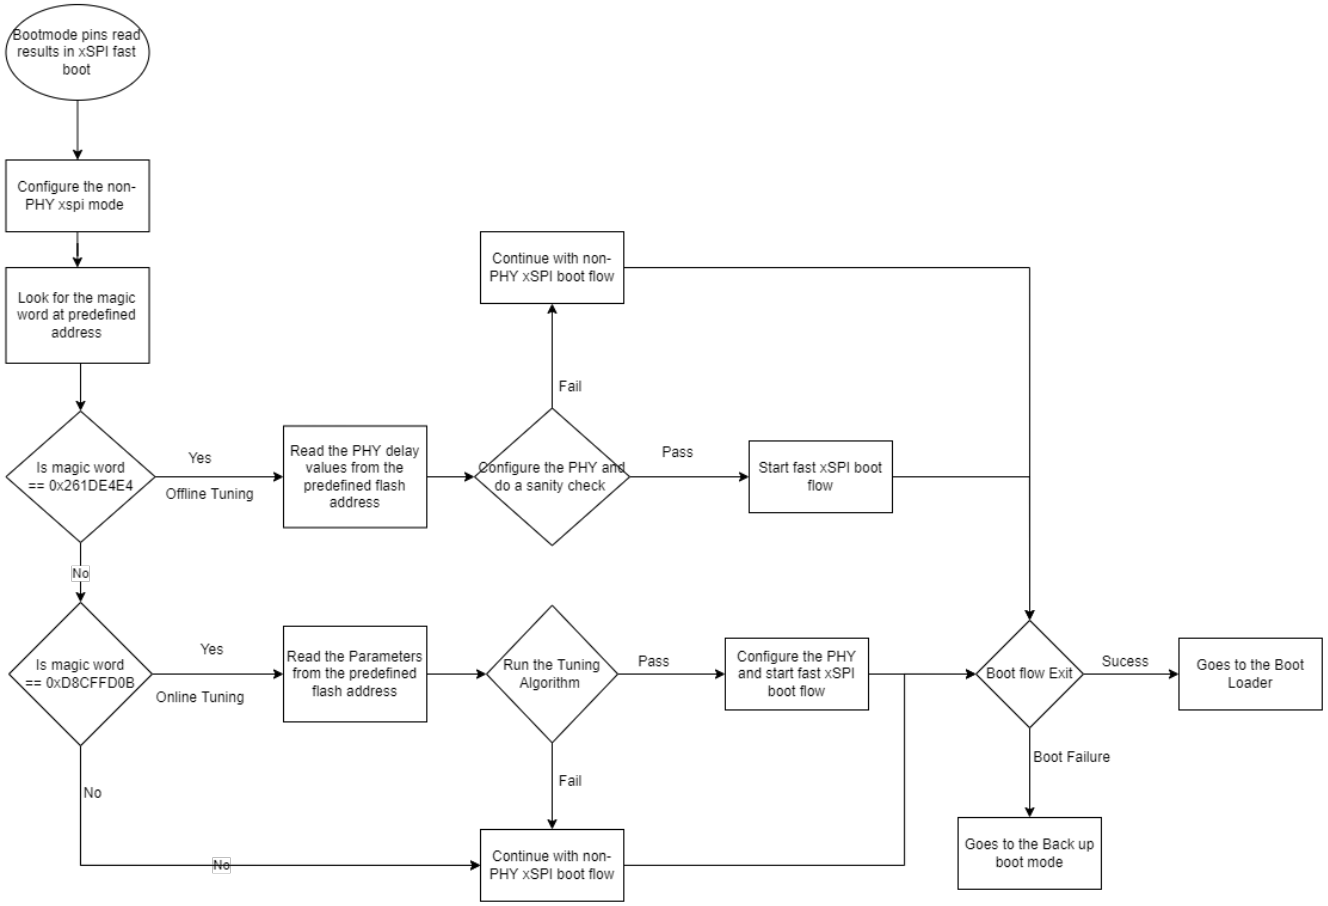

Figure 5-7. Fast-xSPI Control Flow

Table 5-10. Configuration Data for Fast-xSPI Boot

Offset from C0	Bitfields	Description
0 to 127	All	128 byte calibration pattern
128 to 131	All	4 byte Magic Word (defined by ROM). There are two distinct magic words to indicate • Offline tuning - 0x261DE4E4 – byte 128 - E4, 129 - E4, 130 - 1D, 131 - 26 • Online tuning - 0xD8CFFD0B – byte 128 - 0B, 129 - FD, 130 - CF, 131 - D8 The magic word is stored in little endian format. Absence of the magic word leads the ROM use the non-PHY mode.
132 to 135	All	4 byte unsigned int for clock frequency. Only 100Mhz is currently supported. ROM operates at 20 dummy cycles, so the flash should support the chosen frequency at 20 dummy cycles. The clock frequency is stored in little endian format. Any unknown clk freq leads ROM to the non-PHY mode. eg: • 100Mhz - 100000000 - 0x5F5E100 byte 132 - 00, 133 - E1, 134 - F5, 135 – 05

Table 5-10. Configuration Data for Fast-xSPI Boot (continued)

Offset from C0	Bitfields	Description
136	7:0	Flash Parameter Table version 0x00 or 0xFF - Parameter Table version 0 (Not supported for Fast-xSPI boot) 0x01 - Parameter Table version 1 (Latest version supported for Fast-xSPI boot)
137 to 139	All	3 bytes are reserved must be set to 0xFF
140 to 143		3 bytes for Tx_delay, Rx_delay, Rd_delay and one byte for padding. (Only used in case of offline tuning) Byte 143 - Padding must be set to 0xFF.
144 to 158		15 parameters (one byte each) (Only used in case of online tuning)
159	0	Determines if the master delay line locks on a full cycle or half cycle of delay. 0 - Full cycle of Delay 1 - Half cycle of Delay
159	1	DLL bypass mode control Controls the bypass mode of the master and slave DLLs 0 - Master Operation mode 1 - Bypass mode
159	4:2	DLL Phase Detect Selector for sampling clock generation to handle the clock domain crossing between the reference clock and sampling clock. Selects the number of delay elements to be inserted between the phase detect flip-flops: 3'b000 = One delay element 3'b001 = Two delay element 3'b010 = Three delay element 3'b011 = Four delay element 3'b100 = Five delay element 3'b101 = Six delay element 3'b110 = Seven delay element 3'b111 = Eight delay element
159	7:5	Reserved
160	7:0	Secondary search offset: To ensure the search point is valid, we try to do a secondary search. Value provided in this field will be used as an offset which is added to the primary search point TxDLL and then Secondary search is performed from offseted TxDLL point. Supports value from 0 to 127
161		DLL Lock Timeout flag For non-zero flag value, calculated values of DllLockErrCnt and LoopbackLockErrCnt are ignored and 0 is returned instead.
162 to 163		DLL Lock Timeout value in µs.

5.4.1.4 QSPI Boot

Table 5-16 shows configuration pins assignment to functions when boot mode is QSPI using the OSPI module.

Table 5-16. QSPI Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
7	Csel	0	Boot Flash is on CS 0
		1	Boot Flash is on CS 1

Table 5-17 summarizes the OSPI pin configuration done by ROM code for QSPI boot device on port 0.

Table 5-17. QSPI Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Strength Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_CSn0(1)	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1(1)	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

(1) OSPI0_CSn0 and OSPI0_CSn1 are configured as chip select outputs from the OSPI0 host controller, but QSPI boot only uses the chip select output selected via BOOTMODE[7].

Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.1.4.1 QSPI Bootloader Operation

Please refer to Section 5.4.1 for more information that applies to QSPI boot mode

The QSPI boot mode supports the 1S-1S-4S mode only. The ROM will issue a Fast Read Quad Output command (0x6B) followed by a 24 bit (3 byte) address (the starting address is all zeros), followed by 8 dummy cycles. The flash device should then respond with 4-bit data. The frequency of operation during the quad read portion is 50 MHz.

5.4.1.4.1.1 QSPI Initialization Process

In the QSPI boot mode, the ROM Code initializes the OSPI module and the image is read from the QSPI flash connected to the selected chip-select. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM. See Section 5.4.1.4, *QSPI Boot Device Configuration* for OSPI port settings.

A detailed summary of the QSPI boot parameter table and the boot configuration definitions are listed in Section 5.6.3, *QSPI Boot Parameter Table*.

5.4.1.4.1.2 QSPI Loading Process

QSPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

Copyright © 2026 Texas Instruments Incorporated

5.4.1.5 SPI Boot

Table 5-18 shows configuration pins assignment to functions when boot mode is SPI using the OSPI module.

Table 5-18. SPI Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
8	Mode	0	SPI Mode 0
		1	SPI Mode 3
7	Csel	0	Boot Flash is on CS 0
		1	Boot Flash is on CS 1

Table 5-19 summarizes the OSPI pin configuration done by ROM code for SPI boot device on port 0.

Table 5-19. SPI Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_CSn0(1)	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1(1)	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

(1) OSPI0_CSn0 and OSPI0_CSn1 are configured as chip select outputs from the OSPI0 host controller, but SPI boot only uses the chip select output selected via BOOTMODE[7].

Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.1.5.1 SPI Bootloader Operation

Please refer to Section 5.4.1 for more information that applies to SPI boot mode

The SPI boot mode supports the 1S-1S-1S mode only. The Read Command is 8-bits (0x03) followed by a 24 bit (3 byte) address. There are no dummy cycles issued after the read command. The frequency of operation supported is 6.250 MHz. OSPI0_D0 will have data transfers **FROM** the processor **TO** the flash device, and OSPI0_D1 will have data transfers **TO** the processor **FROM** the flash device

5.4.1.5.1.1 SPI Initialization Process

In the SPI boot mode, the ROM Code initializes the OSPI peripheral to SPI mode and the image is read from the flash memory connected to the corresponding OSPI port and chip-select. A detailed summary of the SPI boot parameter table and the boot configuration definitions are listed in Section 5.6.3, *OSPI/QSPI/SPI Boot Parameter Table*. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM.

5.4.1.5.1.2 SPI Loading Process

SPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

Copyright © 2026 Texas Instruments Incorporated

5.4.2 I2C Boot

Table 5-20 shows configuration pins assignment to functions when boot mode is the I2C mode.

Table 5-20. I2C Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
9	Bus reset	0	Hung bus reset attempt after 1 ms
		1	No hung bus reset attempted
7	Address	0	EEPROM's address is 0x50
		1	EEPROM's address is 0x51

The I^{2}C bus is considered inactive if the data line is low and clock remains high for the specified timeout time. Recovery consists of driving the clock a stop condition is detected. A stop condition is a transition on the data line from 0 to 1 while the clock line is high. If the clock line is stuck low there is no way to take control of the bus.

Table 5-21 summarizes the I2C pin configuration done by ROM code for I^{2}C boot device.

Table 5-21. I2C Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
I2C0_SCL	I2C0_SCL	Disable	NA	0	Enable	0	PADCONFIG120
I2C0_SDA	I2C0_SDA	Disable	NA	0	Enable	0	PADCONFIG121

5.4.2.1 I2C Bootloader Operation

5.4.2.1.1 I2C Initialization Process

In the I2C boot mode, the ROM Code configures the Main Domain I2C0 in controller mode.

The boot controller drives the I^{2}C target device where the image is stored. The image is copied to internal RAM, and is executed from there. If the image is not recognized, the ROM will attempt to read the image at offset 0x8000. This is the only redundant image supported by the ROM.

A detailed summary of the I^{2}C boot parameter table and the BOOTMODE pins definitions are listed in Section 5.6.5, *I2C Boot Parameter Table* and Section 5.4.2, *I2C Boot Device Configuration*.

5.4.2.1.1.1 Block Size

ROM code will read 0x800 bytes before processing the data. The last block must be padded to the next 0x800 byte boundary and it must be padded with zeros.

5.4.2.1.1.2 Addressing

The boot code does not support byte address to bus address wrapping. So the maximum image size that can be access is 64 kbytes. For example, if the read address is 0xFF00, the read size is 0x200 and the I^{2}C bus address is 0x50, then 0x100 bytes will be read from 0xFF00 at bus address 0x50, followed by 0x100 bytes from 0x0000 at bus address 0x50. The bus address does not increment when the address rolls over.

5.4.2.1.2 I2C Loading Process

5.4.2.1.2.1 Loading a Boot Image From EEPROM

In this mode, the Main Domain I2C0 peripheral is configured as I^{2}C controller.

ROM Code will start reading from the I^{2}C EEPROM at the specified I^{2}C bus address. This read will be done beginning at the specified base address offset. Data will be read in 2-KB chunks. The data will be stored at the address specified in the boot header. It will continue reading image data until a complete image has been read. When the complete image has been read, the ROM Code will branch to the start address of the image.

Copyright © 2026 Texas Instruments Incorporated

5.4.3 SD Card Boot

Table 5-22 shows configuration pins assignment to functions when boot mode is the SD card boot mode.

Table 5-22. SD Card Boot Configuration Fields

SD Card Boot Configuration Fields			
BOOTMODE Pins	**Field**	**Value**	**Description**
9 (13 [1])	Port	0	Reserved
		1	MMC Port 1 (4 bit width). This bit must be set to 1
7	FS/Raw	0	Filesystem mode
		1	Raw Mode

(1) When MMCSD is the backup mode.

Table 5-23 summarizes the MMCSD pin configuration done by ROM code for SD Card boot on port1 (MMCSD1). SD Card boot on Port 0 (MMCSD0) is not supported.

Table 5-23. SD Card (MMCSD1) Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
MMC1_DAT3	MMC1_DAT3	Disable	NA	0	Enable	0	PADCONFIG137
MMC1_DAT2	MMC1_DAT2	Disable	NA	0	Enable	0	PADCONFIG138
MMC1_DAT1	MMC1_DAT1	Disable	NA	0	Enable	0	PADCONFIG139
MMC1_DAT0	MMC1_DAT0	Disable	NA	0	Enable	0	PADCONFIG140
MMC1_CLK	MMC1_CLK	Disable	NA	0	Enable	0	PADCONFIG141
MMC1_CLKLB	MMC1_CLKLB	Disable	NA	0	Enable	0	PADCONFIG142
MMC1_CMD	MMC1_CMD	Disable	NA	0	Enable	0	PADCONFIG143
MMC1_SDCD	MMC1_SDCD	Disable	NA	0	Enable	0	PADCONFIG144

Note

MMC1_CLKLB signal is not pinned out on the device. The pinmux configuration enables the input buffer of the internal loopback clock.

Note

MMC1_SDWP is not configured by ROM since the ROM never writes to the SD card.

5.4.3.1 SD Card Bootloader Operation

SD Card boot is only available on Port 1 of the MMCSD controller (MMCSD1). The ROM will boot from SD cards using one of these methods:

- User Data Area (UDA) in raw mode
- User Data Area (UDA) in filesystem mode

The ROM is capable of booting from any size SD card because the MMCSD controller is responsible for addressing. Only single data rate with backward compatible interface timing is supported.

The MMCSD module depends on proper voltage level on the SD card detect signal (SDCD). If SDCD=1, the ROM will assume the card is not present and will fail the boot mode.The SDCD must be 0 for the ROM to continue to attempt to boot. Card detect using DAT3 is not supported. If the card is detected, the initial discovery phase is performed:

1. Send CMD 0. (GO IDLE, both for MMC and SD)

Copyright © 2026 Texas Instruments Incorporated

2. Send CMD 55. If the card responds then the card type is assumed to be SD. On timeout the code sends CMD 1. If there is a response then the card type is MMC.

The ROM Code will start reading from the MMCSD memory boot sector, or filesystem, as specified by the BOOTMODE pin (FS/Raw). Only FAT32 and FAT16 formats are supported in filesystem mode. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. In RAW mode, the ROM supports a redundant image at offset 0x400000 in case the initial image fails to be recognized. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

When SD Card boot is used as a backup boot option, only User Data Area (UDA) in filesystem mode is supported. Raw mode is not supported. Additionally, boot will only occur in 1-bit mode during backup booting.

Copyright © 2026 Texas Instruments Incorporated

5.4.4 eMMC Boot

Table 5-24 shows configuration pins assignment to functions when boot mode is the eMMC Boot using a UDA boot mode (BOOTMODE[6:3]=1000b). Note that eMMC Boot using alternate eMMC Boot (BOOTMODE[6:3]=1001b) does not have any extra bootmode configuration fields. See Section 5.4.4.1 for more information.

Table 5-24. eMMC Boot Configuration Fields (UDA mode)

eMMC Boot Configuration Fields			
BOOTMODE Pins	**Field**	**Value**	**Description**
9 (13 [(1)])	Port	0	MMCSD Port 0 (8 bit width). This bit must be set to 0
		1	Reserved
7	FS/Raw	0	Filesystem mode
		1	Raw Mode

(1) When MMCSD Boot is the backup mode.

MMC Port 0 has no pin mux because the pins are dedicated.

5.4.4.1 eMMC Bootloader Operation

Booting from an eMMC device is only available on Port 0 of the MMCSD controller (MMCSD0). Booting from an eMMC device is not available on Port1 (MMCSD1)

The ROM will boot from eMMC devices using one of these methods:

- User Data Area (UDA) in raw mode
- User Data Area (UDA) in filesystem mode
- eMMC bootmode (alternate)

To boot from UDA in either raw or filesystem mode, choose bootmode "MMCSD Boot" (see Table 5-4).

A special alternate boot mode is available with eMMC devices which allows the ROM to boot from an image that is in a separate boot partition in the eMMC. To boot from this mode, choose "eMMC Boot" (see Table 5-4).

The ROM Code will start reading from the memory boot sector, or filesystem, as specified by the BOOTMODE pin (FS/Raw). Only FAT32 and FAT16 formats are supported in filesystem mode. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. In RAW mode, the ROM supports a redundant image at offset 0x400000 in case the initial image fails to be recognized. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

When eMMC boot is used as a backup boot option, only User Data Area (UDA) in filesystem mode is supported. Raw mode is not supported. Additionally, boot will only occur in 1-bit mode during backup booting.

Copyright © 2026 Texas Instruments Incorporated

5.4.5 Ethernet Boot

Table 5-25 shows configuration pins assignment to functions when boot mode is the Ethernet RGMII mode.

Table 5-25. Ethernet RGMII Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
9	Clkout	0	Must be set to 0 to choose external clock
		1	Reserved
8	Delay	0	Must be set to 0 for RGMII with internal Tx delay
		1	Reserved
7	Link info	0	MDIO PHY scan used for link parameters.
		1	Link parameters programmed by the ROM

Table 5-26 shows configuration pins assignment to functions when boot mode is the Ethernet RMII mode.

Table 5-26. Ethernet RMII Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description
9	Clkout	0	50 MHz clock not generated on CLKOUT0
		1	50 MHz clock generated on CLKOUT0
8	Clk src	0	External clock source for RMII1_REF_CLK
		1	Internal clock source for RMII1_REF_CLK
7	RMII	0	This bit must be set to 0
		1	Reserved

Table 5-27. Ethernet RMII Clocking

BOOTMODE Pin 9 (Clk out)	BOOTMODE Pin 8 (Clk src)	Description
0	0	50MHz external source to RMII_REF_CLK and to external Ethernet PHY input clock (CLKOUT0 is unused) These are the recommended settings
0	1	Not a valid configuration
1	0	CLKOUT0 is configured to 50MHz and connect to both RMII1_REF_CLK and to external Ethernet PHY input clock
1	1	Not a valid configuration

Table 5-28 shows configuration pins assignment to functions when the backup boot mode Ethernet. The Interface configuration field chooses which interface will be used (RGMII or RMII)

Table 5-28. Ethernet Backup Boot Configuration Field

BOOTMODE Pins	Field	Value	Description
13	Interface	0	RGMII with internal TX delay
		1	RMII with external clock source

Table 5-29 summarizes the RGMII pin configuration done by ROM code for Ethernet boot device on RGMII port.

Table 5-29. RGMII Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
RGMII1_TX_CTL	RGMII1_TX_CTL	Disable	NA	0	Disable	0	PADCONFIG75
RGMII1_TXC	RGMII1_TXC	Disable	NA	0	Disable	0	PADCONFIG76
RGMII1_TD0	RGMII1_TD0	Disable	NA	0	Disable	0	PADCONFIG77

MDIO0_MDC	MDIO0_MDC	Disable	NA	0	Disable	0	PADCONFIG88

5.4.5.1 Ethernet Bootloader Operation

5.4.5.1.1 Ethernet Initialization Process

When the device is set to boot through the Ethernet mode, the ROM Code configures the Ethernet module and the interface mode (RMII, RGMII) according the the BOOTMODE pin settings, see Section 5.4.5, *Ethernet Boot Device Configuration*. Also consult the boot parameter table for the Ethernet boot, see Section 5.6.7, *Ethernet Boot Parameter Table*.

When Link Info = 0, the link parameters are read using MDIO scan. This is the typical setting when using an external PHY. With these parameters, the ROM identifies the PHY and establishes link with the supported speed and duplex mode.

Copyright © 2026 Texas Instruments Incorporated

When Link Info = 1, no MDIO scan is performed, and the link parameters are programmed by the ROM based on the RGMII status register. This is the typical setting when configured as a MAC to MAC RGMII interface whereby RGMII pins of two devices can be connected diretly and establish link in force mode. The chosen configuration will be Gigabit, full duplex mode.

Note that booting from RGMII requires that an attached PHY be configured for RGMII-ID Mode immediately upon exiting reset. The ROM will not make this configuration change to the PHY.

The ROM will setup RGMII mode enabling internal delay mode.

5.4.5.1.2 Ethernet Loading Process

After device configuration, the bootloader performs a standard BOOTP/TFTP boot. The device sends a BOOTP request with its MAC address to a host TFTP server to be assigned an IP from a pool of addresses. The timeout for each BOOTP packet is 4 seconds, and the ROM will attempt 10 BOOTP retries, after which the boot mode will fail. If the connection is established, the device initiates a TFTP download and is able to receive image data encapsulated in Ethernet packets, see Section 5.4.5.1.2.1. There is a timeout of 1 second to receive a response for the READ request, and the ROM will retry the READ request 10 times, after which the boot mode will fail. If TFTP download is successful, data received is stripped of its network headers and the boot data is stored in internal RAM. When the transfer completes and the image is found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

5.4.5.1.2.1 Ethernet Boot Data Formats

Ethernet boot uses the BOOTP/TFTP protocol for downloads. Only IPv4 is supported.

5.4.5.1.2.1.1 Limitations

- Received packets cannot be IP fragmented (should not be a problem in most systems since the BOOTP/TFTP packets have fixed lengths of small size)
- Only DIX Ethernet headers are supported.
  - 802.3 with SNAP/LLC not supported
  - DIX Ethernet with VLAN not supported
  - 802.3 with VLAN and SNAP/LLC not supported

5.4.5.1.2.1.2 BOOTP Request

5.4.5.1.2.1.2.1 MAC Header (DIX)

- Destination MAC = value from parameter table (default is broadcast)
- Source MAC = value from parameter table (default is e-fuse value)
- Type = IPv4 (0x0800)

5.4.5.1.2.1.2.2 IPv4 Header

- Version = 4
- Header length = 0
- TOS = 0
- Len = computed during operation
- ID = 0x0001
- Flags + Fragment offset = 0
- TTL = 0x10
- Protocol = UDP (17)
- Header checksum = Computed during operation
- SRC IP = 0.0.0.0
- Dest IP = 255.255.255.255

5.4.5.1.2.1.2.3 UDP Header

- Source port = BOOTP client (68 decimal)
- Destination Port = BOOTP server (67 decimal)
- Length = computed during operation

Copyright © 2026 Texas Instruments Incorporated

- Checksum = computed during operation

5.4.5.1.2.1.2.4 BOOTP Payload

- Opcode = Request (1)
- HW Type = Ethernet (1)
- HW Addr Len = 6
- Hop Count = 0
- Transaction ID = 1
- Number of seconds = 0
- Client IP = 0.0.0.0
- Your IP = 0.0.0.0
- Server IP = 0.0.0.0
- Gateway IP = 0.0.0.0
- Client HW Address = Device MAC address (from parameter table)
- Server hostname = NULL
- Filename = NULL
- Option 60, Vendor ID string, from parameter table
- Option 61, Client ID string, from parameter table

5.4.5.1.2.1.2.5 TFTP

There are no ROM code specific TFTP configurations.

5.4.5.1.3 Ethernet Hand Over Process

Once the ROM Code receives the valid packet, it decodes it to get the image sections and loads them in the appropriate memory location. After the image is loaded and validated, the ROM Code starts the boot image execution.

Copyright © 2026 Texas Instruments Incorporated

5.4.6 USB Boot

Table 5-31 shows configuration pins assignment to functions when boot mode is the USB mode.

Table 5-31. USB Boot Configuration Fields

USB Configuration Fields for Primary Boot Mode			
BOOTMODE Pins	**Field**	**Value**	**Description**
9	CoreVoltage	0	Must be set
		1	Reserved
8 (13[1])	Mode	0	DFU (USB device firmware upgrade)
		1	Host (MSC boot)
7	Lane Swap	0	D+/D- lines are not swapped
		1	D+/D- lines are swapped

(1) When USB is the backup mode.

Table 5-32 summarizes the USB pin configuration done by ROM code for USB boot device on port 0.

Table 5-32. USB Port 0 Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
USB0_DRVVBUS	USB0_DRVVBUS	Disable	NA	0	Disable	0	PADCONFIG149

Note

Note that other USB pins do not have pin mux options. USB_DRVVBUS is configured in DFU mode even though it is not used.

Note on USB backup boot:

- Lane Swap (D+/D- lines) are not allowed

Configurability (pins) of these options do not exist in the USB backup boot mode.

CAUTION

A USB Type-AB connector should not be connected to another host when the device is booting as a USB Host. This will prevent two USB power sources from being connected together.

5.4.6.1 USB Bootloader Operation

The USB boot mode is used to read the boot image from external USB host.

See Section 5.4.6, *USB Boot Device Configuration* and Section 5.6.10, *USB Boot Parameter Table* for the available configuration options.

More information about USB DFU protocol can be found at http://www.usb.org/sites/default/files/DFU_1.1.pdf.

In DFU mode, the ROM will attempt an enumeration for 60 seconds, after which the boot mode will fail. If a successful enumeration is achieved, the ROM Code will start reading from the external host as specified by the BOOTMODE pins. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

5.4.6.1.1 USB-Specific Attributes

5.4.6.1.1.1 DFU Device Mode

- Vendor ID = 0x451
- Product ID = 0x6165
- Device ID = 0

Copyright © 2026 Texas Instruments Incorporated

5.4.7 UART Boot

ROM Code always configures the UART port to 115200 kbaud, 8-n-1 mode, and the XMODEM protocol is used to transfer the boot data.

Table 5-33 summarizes the UART pin configuration done by ROM code for UART host on port 0.

Table 5-33. UART Port 0 Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
UART0_TXD	UART0_TXD	Disable	NA	0	Disable	0	PADCONFIG115
UART0_RXD	UART0_RXD	Disable	NA	0	Enable	0	PADCONFIG114

5.4.7.1 UART Bootloader Operation

5.4.7.1.1 Initialization Process

In the UART boot mode, the selected UART module (port) is the only peripheral configured. The baud rate, data, parity, and stop bits are configured based on the information in the UART boot parameter table. The boot parameter table definitions and the boot configuration values that can be set are in Section 5.4.7, *UART Boot Device Configuration* and Section 5.6.4, *UART Boot Parameter Table*.

Once the ROM Code configures the UART, it sends the UART pings for few seconds, which can be seen in the host. The pings consist of an ASCII capital *C* character. The UART boot mode supports only the CRC mode of XMODEM and does not support CHECKSUM mode. Both 128 and 1024 byte block sizes are supported.

5.4.7.1.2 UART Loading Process

Before the ping from the device stops, load the boot image from the host using the XMODEM protocol. Until UART boot data is sent from the host, the ROM code will continue to send pings for 120 seconds before aborting and moving to the secondary boot mode (if applicable).

Note

The device also implements a separate 180 watchdog timer. If UART boot is the primary boot mode, and no secondary boot mode is selected, the subsequent UART boot will timeout after 60sec due to the watchdog timer.

5.4.7.1.2.1 UART XMODEM

The XMODEM protocol is used to transfer boot data. Only CRC mode is supported (not checksum), with both 128- and 1024-byte block sizes. The general, format of received frames is shown in Table 5-34 and Table 5-35.

Table 5-34. XMODEM 1024- and 128-byte Data Frames

STX	Block Num	Inv Block Num	1024 data bytes		CRC	CRC
SOH	Block Num	Inv Block Num	128 data bytes	CRC	CRC	

Table 5-35. XMODEM Data Frame Fields

Field	Value	Description
STX	0x02	The start character for 1024-byte CRC data blocks
SOH	0x01	The start character for 128-byte CRC data block
Block Num	0x01-0xFF – 0x00	The block number. The first block has value 1, and the block number wraps around 0xFF to 0
Inv Block Num	0xFE-0x00	The inverse block number (bit inverse of the block number)
CRC	Calculated	The 16-bit CRC generated from the polynomial 0x1021

The XMODEM protocol is implemented as a half-duplex protocol as shown in Table 5-36.

Copyright © 2026 Texas Instruments Incorporated

Table 5-36. Example of XMODEM Transfer protocol

Transmitter Sends		Receiver Sends
	←	Ping (‘C’)
Frame 1	→	
	←	ACK (or NACK)
Frame 2	→	
	←	ACK (or NACK)
EOT	→	
	←	ACK (or NACK)

5.4.7.1.3 UART Hand-Over Process

Once the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

5.4.8 GPMC NOR Boot

There are no configuration fields for this boot mode. GPMC NOR boot only supports 16-bit non-mux memory.

Table 5-37 summarizes the GPMC pin configuration done by ROM code for GPMC NOR boot.

Table 5-37. GPMC NOR Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
GPMC0_AD0	GPMC0_AD0	Disable	NA	0	Enable	0	PADCONFIG15
GPMC0_AD1	GPMC0_AD1	Disable	NA	0	Enable	0	PADCONFIG16
GPMC0_AD2	GPMC0_AD2	Disable	NA	0	Enable	0	PADCONFIG17
GPMC0_AD3	GPMC0_AD3	Disable	NA	0	Enable	0	PADCONFIG18
GPMC0_AD4	GPMC0_AD4	Disable	NA	0	Enable	0	PADCONFIG19
GPMC0_AD5	GPMC0_AD5	Disable	NA	0	Enable	0	PADCONFIG20

Table 5-37. GPMC NOR Boot Pin Usage (continued)

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
GPMC0_BE0n_CLE	GPMC0_BEOn_CLE	Disable	NA	0	Disable	0	PADCONFIG36
GPMC0_BE1n	GPMC0_BE1n	Disable	NA	0	Disable	0	PADCONFIG37
GPMC0_CSn0	GPMC0_CSn0	Disable	NA	0	Disable	0	PADCONFIG42

Note

Only 21 address lines (GPMC0_A0 – GPMC0_A20) are used because the GPMC0_A21 and GPMC0_A22 lines are muxed with GPMC0_WAIT1 and GPMC0_WPn respectively.

GPMC0_A20 is muxed with GPMC0_CSn3, and ROM uses GPMC0_A20 for this address line. Thus, no CSn3 support when using GPMC NOR boot.

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.8.1 GPMC NOR Bootloader Operation

In this mode, the ROM Code configures the GPMC interface based on the configuration parameters specified in the boot parameter table for the GPMC NOR boot mode Section 5.6.11, see*GPMC NOR Boot Parameter Table*.

Timing registers are programmed as follows for NOR flash boot:

Table 5-38. GPMC NOR Timing Configuration

GPMC register	Value
GPMC_CONFIG1	0x00001010
GPMC_CONFIG2	0x00101c01
GPMC_CONFIG3	0x23060917
GPMC_CONFIG4	0x1005bc1a
GPMC_CONFIG5	0x011b111e
GPMC_CONFIG6	0x8f070000
GPMC_CONFIG7	0x00000c50

GPMC NOR boot mode is not executable-in-place (XIP). ROM code first copies boot image into on-chip RAM and then executes it. Only non-muxed memory is supported. If the initial image at offset 0x0 is not recognized, the ROM will attempt to read a redundant image from offset 0x100000. This is the only redundant image supported by the ROM.

Copyright © 2026 Texas Instruments Incorporated

5.4.9 GPMC NAND Boot

Table 5-39 summarizes the GPMC pin configuration done by ROM code for NAND boot.

Table 5-39. GPMC NAND Boot Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
GPMC0_AD0	GPMC0_AD0	Disable	NA	0	Enable	0	PADCONFIG15
GPMC0_AD1	GPMC0_AD1	Disable	NA	0	Enable	0	PADCONFIG16
GPMC0_AD2	GPMC0_AD2	Disable	NA	0	Enable	0	PADCONFIG17
GPMC0_AD3	GPMC0_AD3	Disable	NA	0	Enable	0	PADCONFIG18
GPMC0_AD4	GPMC0_AD4	Disable	NA	0	Enable	0	PADCONFIG19
GPMC0_AD5	GPMC0_AD5	Disable	NA	0	Enable	0	PADCONFIG20
GPMC0_AD6	GPMC0_AD6	Disable	NA	0	Enable	0	PADCONFIG21
GPMC0_AD7	GPMC0_AD7	Disable	NA	0	Enable	0	PADCONFIG22
GPMC0_ADVn_ALE	GPMC0_ADVn_ALE	Disable	NA	0	Disable	0	PADCONFIG33
GPMC0_OEn_Ren	GPMC0_OEn_Ren	Disable	NA	0	Disable	0	PADCONFIG34
GPMC0_Wen	GPMC0_Wen	Disable	NA	0	Disable	0	PADCONFIG35
GPMC0_BEOn_CLE	GPMC0_BEOn_CLE	Disable	NA	0	Disable	0	PADCONFIG36
GPMC0_WAIT0	GPMC0_WAIT0	Disable	NA	0	Enable	0	PADCONFIG38
GPMC0_CSn0	GPMC0_CSn0	Disable	NA	0	Disable	0	PADCONFIG42

5.4.9.1 GPMC NAND Bootloader Operation

Timing registers are programmed as follows for NAND flash boot:

Table 5-40. GPMC NAND Timing Configuration

GPMC register	Value
GPMC_CONFIG1	0x00000812
GPMC_CONFIG2	0x00080b00
GPMC_CONFIG3	0x22080810
GPMC_CONFIG4	0x05006890
GPMC_CONFIG5	0x0107080b
GPMC_CONFIG6	0x80000180
GPMC_CONFIG7	0x00000f50

GPMC NAND boot only supports boot from ONFI 1.0 compatible 8 bit parallel NAND memory up to 2Gbytes in size connected to GPMC CS0 with the following geometries:

- 2Kbyte page and spare area of at least 64 bytes or
- 4Kbyte page size and spare area of at least 128 bytes.
- Non-ECC part only:
  - ROM uses ELM to handle ECC
  - ECC is BCH8 using D[7:0] for data
  - The param page CRC is checked and in case of failure the redundant page is used

GPMC is setup to comply with mode 0 timing for NAND flash.

Copyright © 2026 Texas Instruments Incorporated

5.4.10 Serial NAND Boot

Serial NAND Configuration Fields table shows configuration pins assignment to functions when boot mode is Serial NAND.

Table 5-41. Serial NAND Configuration Fields

BOOTMODE Pins	Field	Value	Description
8	Read Mode 2	0	Reserved (Read mode is taken from Read Mode 1
		1	SPI/ 1-1-1 mode (Read mode is taken from Read Mode 2 and Read Mode 1 is ignored)
7	Read Mode 1	0	OSPI/ 1-1-8 Mode (valid only when Read Mode 2 is 0)
		1	OSPI/ 1-1-4 Mode (valid only when Read Mode 2 is 0)

Serial NAND Pin Usage table summarizes the pin configuration done by ROM code for the Serial NAND device.

Table 5-42. Serial NAND Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel	Pad Configuration Register
OSPI0_CLK	OSPI0_CLK	Disable	NA	0	Disable	0	PADCONFIG0
OSPI0_DQS	OSPI0_DQS	Disable	NA	0	Enable	0	PADCONFIG2
OSPI0_D0	OSPI0_D0	Disable	NA	0	Enable	0	PADCONFIG3
OSPI0_D1	OSPI0_D1	Disable	NA	0	Enable	0	PADCONFIG4
OSPI0_D2	OSPI0_D2	Disable	NA	0	Enable	0	PADCONFIG5
OSPI0_D3	OSPI0_D3	Disable	NA	0	Enable	0	PADCONFIG6
OSPI0_D4	OSPI0_D4	Disable	NA	0	Enable	0	PADCONFIG7
OSPI0_D5	OSPI0_D5	Disable	NA	0	Enable	0	PADCONFIG8
OSPI0_D6	OSPI0_D6	Disable	NA	0	Enable	0	PADCONFIG9
OSPI0_D7	OSPI0_D7	Disable	NA	0	Enable	0	PADCONFIG10
OSPI0_CSn0(1)	OSPI0_CSn0	Disable	NA	0	Disable	0	PADCONFIG11
OSPI0_CSn1(1)	OSPI0_CSn1	Disable	NA	0	Disable	0	PADCONFIG12

(1) Both OSPI0_CSn0 and OSPI0_CSn1 are configured as chip select outputs from the OSPI0 host controller, but Serial NAND boot only uses OSPI0_CSn0. It is not possible to select OSPI0_CSn1 as a chip select option for Serial NAND boot.

Note

All signals in the table will be configured even though some may not be used by this particular boot mode.

5.4.10.1 Serial NAND Bootloader Operation

Serial NAND defines 1S-1S-1S mode for general backwards compatibility, and 1S-1S-8S for maximum throughput (S here means *S*ingle Data rate). Serial NAND memory array is organized into pages of size 2KB/4KB. Read is a two-step process where a complete page is first read into flash's internal buffer/cache using Page read command and then the host controller reads from internal buffer in 1- or 4- or 8-bit mode using the read commands. Page read command that is issued is 0x13, followed by 24 address bits. The frequency of operation supported is 50 MHz.

For 1S-1S-1S mode of operation (Bit-width =1, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x0B, followed by address bits and 8 dummy cycles.

For 1S-1S-8S mode of operation (Bit-width =8, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x8B, followed by address bits and 8 dummy

Copyright © 2026 Texas Instruments Incorporated

cycles. Additionally, flash is configured in 8-bit mode after POR through volatile configuration register if the manufacturer is Winbond.

For 1S-1S-4S mode of operation (Bit-width =4, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x6B, followed by address bits and 8 dummy cycles. Note that in 8-bit mode pin mux is done for all 8 OSPI data lines and in 4-bit/1-bit mode pin mux is done for 4 OSPI data lines. This is done to disable the HOLD functionality feature in 1-bit mode.

Serial NAND boot expects ECC to be auto-managed by the flash. Most of the flashes have the ECC enabled by default and can do 1-bit correction and 2-bit detection for ECC errors. ROM checks for 2-bit ECC error via status register 3 (address 0xC0) bit 5 after every page load. In case of 2-bit ECC error the boot will fail and ROM will take the fallback option.

Serial NAND boot also manages bad blocks that can be present in the flash at time of shipment or develop during the lifetime. Bad block marker is a non-FFh data byte stored at Byte 0 of spare area of Page 0 for each bad block and ROM checks for the same while reading the first page of a memory block. ROM will skip the particular block if it is marked as bad and move to the next one.

The Serial NAND driver in ROM does not support devices that have multiple planes as they require special handling to read even numbered blocks

5.4.10.2 Serial NAND Initialization Process

In the OSPI boot mode, the ROM Code initializes the OSPI module and the image is read from the OSPI flash connected to the selected chip-select. If the image fails to be read correctly from offset 0x0 of the flash memory, the ROM will attempt to obtain the image at offset 0x400000. This is the only redundant image location supported by the ROM. See Section 5.4.1.1, *OSPI Boot Device Configuration* for OSPI port settings.

A detailed summary of the OSPI boot parameter table and the boot configuration definitions are listed in Section 5.6.3, *OSPI Boot Parameter Table*.

5.4.10.3 Serial NAND Loading Process

OSPI boot mode is not eXecute-In-Place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

Copyright © 2026 Texas Instruments Incorporated

5.4.11 No boot/Development boot

Table 5-43 shows configuration pins assignment to functions when boot mode is the No-boot mode.

Table 5-43. No-boot/Dev-boot Configuration Fields

Field	Value	Description
No/Dev	0	Development Boot
	1	No boot
ARM/Thumb	0	ARM mode
	1	Thumb mode

These boot modes are useful for debugging purposes to preclude the execution of the ROM.

During the Development boot (BOOTMODE[7] = 0), the SMS M4F ROM code will act as if boot of the primary image has completed, and the SMS M4F ROM then will be waiting for a firmware load message from DM R5. Thus the user can load a standard u-boot/SPL image to the DM R5 RAM. U-boot/SPL will then load the SMS firmware and complete the full boot.

In No-boot (BOOTMODE[7] = 1), both the SMS M4F and DM R5 ROMs are bypassed and both CPUs are held in a dummy branch-to-self loop. No-boot is the most minimal device touch state by the ROM - only minimal hardware configurations are done and none of the PLLs is locked/configured. No-boot is suitable if user wants to load his own PLL, Pad config, and other basic settings.

Copyright © 2026 Texas Instruments Incorporated

5.5 PLL Configuration

ROM code must be aware of the reference clock provided to PLLs. That is, the speed of the quartz crystal, or the clock supplied by an external clock oscillator. On how to indicate the PLL reference clock, see PLL Reference Clock Selection

ROM code configures only PLLs which are required during boot. Therefore, if a PLL is required for the backup boot mode but not the primary boot mode, and if the backup boot mode never executes, then the PLLs required for backup boot are not enabled.

The following tables show the HSDIV values that are programmed by the R5 ROM if a boot mode uses it. A value of NA means that the ROM does not program that HSDIV

Table 5-44. MAIN_PLL0 (MAIN PLL) (2000MHz)

PLL POSTDIV	HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
0	HSDIV0	4	500	MAIN SYSCLK0
0	HSDIV1	10	200	OSPI
0	HSDIV2	0	NA	WKUP_CLKOUT
0	HSDIV3	15	133	GPMC NOR/GPMC NAND
0	HSDIV4	0	NA	MCAN
1	HSDIV5	5	200	MMCSD0
1	HSDIV6	0	NA	CPTS
1	HSDIV7	4	250	TIMER
1	HSDIV8	0	NA	USB0
1	HSDIV9	0	NA	Reserved

Table 5-45. MAIN_PLL1 (PER0 PLL) (1920MHz)

PLL POSTDIV	HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
0	HSDIV0	10	192	UART
0	HSDIV1	12	160	Configured but not used
0	HSDIV2	0	NA	WKUP_CLKOUT
0	HSDIV3	0	NA	TIMER
0	HSDIV4	0	NA	Reserved
1	HSDIV5	0	NA	OSPI
1	HSDIV6	0	NA	McASP

Table 5-46. MAIN_PLL2 (PER1 PLL) (2000MHz)

PLL POSTDIV	HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
0	HSDIV0	0	NA	Reserved
0	HSDIV1	8	250	CPSW0
0	HSDIV2	10	200	MMCSD1
0	HSDIV3	0	NA	DebugSS
0	HSDIV4	0	NA	Video Encoder/Decoder
1	HSDIV5	0	NA	MCSPI
1	HSDIV6	0	NA	TIMER
1	HSDIV7	0	NA	GPMC
1	HSDIV8	0	NA	McASP
1	HSDIV9	0	NA	WKUP_CLKOUT

Copyright © 2026 Texas Instruments Incorporated

Table 5-47. MAIN_PLL15 (2400MHz)

HSDIV	Value	Frequency(MHz)	Boot Peripheral/IP
HSDIV0	5	400	HSM/SMS
HSDIV1	5	400	SA3_UL PKA
HSDIV2	3	800	DM

Note

All other PLLs are not used or programmed by the ROM

Note

The bringup and configuration of bootmode-specific PLLs by ROM code will result in a bootmode-specific device clocking setup which for example has an impact on which peripheral modules can readily be clocked and used by SBL/SPL prior to loading and bringing up System Firmware (SYSFW)

Copyright © 2026 Texas Instruments Incorporated

5.6 Boot Parameter Tables

The boot parameter tables direct the main module boot process. On cold boot the tables are created based on pin strapped values (see Section 5.3, *Boot Mode Pins*) and built-in data. The ROM Code supports two parameter tables stored as an array in a fixed memory address in the MSRAM, each of size 512 bytes. The ROM will attempt to boot using the primary table. On boot failure, ROM Code will retry using the second table.

Using two tables handles two cases.

- The first is in initial board manufacture where the primary boot table specifies boot from a flash device, and the flash is blank. ROM Code would then switch to the secondary boot mode which would receive the image externally (Ethernet, USB, UART) and this image would flash the boot image.
- The second case is failure due to total flash corruption. In all flash parameter tables there exist backup addresses within the primary boot mode. This covers the problem of a flash update failure with a backup image present on the same flash device.

The boot tables reside at a fixed location in memory which is described in Section 5.8.2, *Global Memory Addresses Used by ROM Code*.

5.6.1 Common Header

These boot parameter tables have certain parameters common across all the boot modes, while the rest of the parameters are unique to the boot modes. The common entries in the boot parameter table are shown in Table 5-48.

Table 5-48. Boot Parameter Table Common Header

Byte Offset	Size (bytes)	Name	Description
0	2	Length	The length of the table
2	2	Checksum	Ones complement checksum over length bytes in the table. If 0 the checksum is not validated.
4	2	Peripheral	Identifies the boot peripheral and format of the table after the common header. See Table 5-49
6	2	Reserved	Reserved
8	4	Timeout	Timeout for this boot mode, in milliseconds
12	4	Magic	Magic value 0x01AD0911
16	40	PLL Config 0	PLL Configuration 0. See Table 5-50
56	40	PLL Config 1	PLL Configuration 1
96	40	PLL Config 2	PLL Configuraiton 2
136	40	PLL Config 3	PLL Configuration 3
176	40	PLL Config 4	PLL Configuration 4
216	40	PLL Config 5	PLL Configuration 5

Table 5-49 lists the possible boot modes used in the boot parameter tables.

Table 5-49. Boot Peripheral Selection

Peripheral Field Value	Description
0	Sleep (No boot)
10	Ethernet Reserved
20	Ethernet BOOTP/TFTP (general)
21	Ethernet RGMII specific
22	Ethernet RMII specific
30	Reserved
31	Reserved
32	Reserved
40	I2C

Table 5-49. Boot Peripheral Selection (continued)

Peripheral Field Value	Description
50	SPI
60	UART
70	USB DFU
71	USB Reserved
72	USB Host MSC
80	QSPI
85	OSPI
90	Reserved
100	MMCSD Card (general)
101	eMMC (general)
102	MMC 1-bit
103	MMC 4-bit
104	MMC 8-bit
110	GPMC NOR
120	Reserved
130	xSPI
140	GPMC NAND
150	Serial NAND
160	Fast-xSPI

5.6.2 PLL Setup

Table 5-50 through Table 5-54 describe the PLL configuration fields.

Table 5-50. Boot Parameter Table PLL Configuration

Byte Offset	Size (bytes)	Name	Description
0	1	Domain/cfg	See Table 5-51
1	1	Pll number	PLL number indexed from 0.
2	1	Input source	See Table 5-53
3	1	Pll Type	This field must be 1 to indicate an SCPLL
4	4	Input Ref Clock	The PLL input clock, in Q16.16 format
8	4	Feed back divider, integer part	Integer value of feedback divider
12	4	Feed back divider, fractional part	Fractional portion of feedback divider. Total divider is the Integer part + (Fractional part / 2^{24})
16	1	Ref divider	Input clock pre-divider
17	1	Post divider 1	Output post divider 1
18	1	Post divider 2	Output post divider 2
19	1	Reserved	Reserved
20	2	Hsdiv Enable	Bit map. A set bit indicates that the corresponding hsdiv is enabled.
22	2	Reserved	Reserved
24	16	Hsdiv[16]	Array of hs divider values.

Table 5-51. PLL Domain and Enable Configuration

Field	Value	Description
Source Type	0	Source is HFOSC
	1	Source is external pin
	2	Reserved
	3-7	Reserved
Source Index	0-31	Source index (HFOSC[0-31] or pin[0-31], depending on Source Type) HFOSC[0] – WKUP_HFOSC0 HFOSC[1] – HFOSC1 (in MAIN domain) PIN[1] – EXT_REFCLK1 pin (not all PLLs, see *Clocking*

5.6.3 OSPI/QSPI/SPI Boot Parameter Table

Table 5-55 shows the boot parameter table for OSPI, QSPI, or SPI boot. Must be preceded with the common boot parameters described in Table 5-48.

Table 5-55. OSPI/QSPI/SPI Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode on	From Pins	If non-zero, the mode byte will be sent
258	1	Instruct Width	From Pins	Number of pins used to send instructions (1, 2, 4, 8)
259	1	Address Width	From Pins	Number of pins used to send address (1, 2, 4, 8)
260	1	Data Width	From Pins	Number of pins used to received data (1, 2, 4, 8)
261	1	Address Size	24	24, and 32 bits are the valid address sizes
262	1	Mode	0	OSPI clock polarity and phase mode
263	1	CSEL	From Pins	Chip select number (0–3)
264	1	Read Cmd	From Pins	Command used to read read data
265	1	Mode byte	0	Value used for the mode byte (when active)
266	1	Dummy Cycles	From pins	Number of dummy cycles sent after the read command
267	1	clkRecovery	From pins	Clock recovery
268	1	dqsEnable	0	Enable DQS
269	1	Reserved	0	Reserved
270	2	Module Freq	0	The OSPI module frequency after PLL enable, in kHz. If 0, ROM code uses the value from the module clock tables.
272	4	Bus Frequency	From pins	The OSPI bus frequency, in kHz
276	4	Delay	0x08080808 or 0x01010101	The chip select read delays. Default value is based on the read command

Copyright © 2026 Texas Instruments Incorporated

Table 5-55. OSPI/QSPI/SPI Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
280	4	Tap Delay	0xFFFFFFFF	The read tap selection. If 0xFFFFFFFF, the ROM code will scan the taps to find the best delay. The result will then overwrite the value in this table.
284	4	Internal Clk	From pins	0 = external (dqs) 1 = internal
288	4	notDAC	From pins	When 0, DAC mode is used
292	4	Read Index	0	Index to the active read address (0-1)
296	4	Read Addr 0	0x000000	The initial flash read address
300	4	Read Addr 1	0x400000 (0x4000 SPI)	Backup read address
304	4	Reserved	0	Reserved
308	4	Reserved	0	Reserved

5.6.4 UART Boot Parameter Table

Table 5-56 shows the boot parameter table for UART boot. Must be preceded with the common boot parameters described in Table 5-48.

Table 5-56. UART Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Magic	0x49	Required Magic value
257	1	Protocol	63 (0x3F)	Specifies the transfer protocol = XMODEM
258	2	Reserved	0	Reserved
260	1	Max error Count	10	Error count resulting in boot abort
261	1	Ack timeout	3	Timeout in seconds on ack
262	1	Char timeout	20	Inter-character timeout in milliseconds
263	1	Reserved	0	Reserved
264	4	Port	From Pins	Physical port number
268	4	Mod Ref Clk	48000	Module reference clock, in kHz
272	4	Data Rate	115200	Baud rate (bps)
276	1	Parity	0	0=none, 1=odd, 2=even
277	1	Data bits	8	Only 8 data bit width is supported
278	1	Stop bits	2	Stop bits in Q7.1 format (2 = 1 stop bit)
279	1	Flow Control	0	0=none, 1= RTS/CTS
280	1	Over sample	16	Only 16× and 13× oversample are supported
281	1	Magic 2	0xB7	Required magic value

5.6.5 I2C Boot Parameter Table

Table 5-57 shows the boot parameter table for I2C boot. Must be preceded with the common boot parameters described in Table 5-48.

Table 5-57. I2C Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode	From Pins	0x4E = I2C Controller, 0x72 = I2C target
258	1	Dev Addr	From Pins	I2C address when target mode (0x10 or 0x11)
259	1	Reserved	0	Reserved

Copyright © 2026 Texas Instruments Incorporated

Table 5-57. I2C Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
260	4	Mod Clock	0	I2C Module input clock. If 0, it is computed by ROM code.
264	2	Bus Freq	400	I2C Controller mode bus frequency, in kHz
266	2	Bus Addr	From Pins	I2C Controller mode storage device's address (0x50 or 0x51)
268	2	Read Index	0	Index to the active read offset (0 or 1)
270	2	Read Offset 0	0x0000	I2C Controller mode read offset
272	2	Read Offset 1	0x8000	I2C Controller mode backup read offset
274	2	Reserved	0	Reserved
276	2	Reserved	0	Reserved
280	2	Busy Timeout	From pins	Number of µs before a bus recovery is attempted. In units of microseconds in Q3 number format. Value of 0 disables bus recovery attempts.

5.6.6 MMCSD/eMMC Boot Parameter Table

MMCSD/eMMC Boot Parameter Table shows the boot parameter table for eMMC, MMC or SD card boot. Must be preceded with the common boot parameters described in Table 5-48.

Table 5-58. MMCSD/eMMC Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	From Pins	Physical port number
257	1	eMMC	From Pins	0 = SD/MMC, else eMMC
258	1	bootAck	1 for eMMC 0 for SD/MMC	If 1 and in eMMC mode the controller expects a boot ack from the eMMC
259	1	Media	1 for eMMC 0 for SD/MMC	0 = auto detect card type 1 = MMC 2 = SD
260	1	busWidth	8 for eMMC From Pins for SD/MMC	Number of data pins (1, 4, or 8). If 0, max supported pins of the port are used.
261	1	bootAlt	1 for eMMC 0 for SD/MMC	If 1 and in eMMC mode, the controller uses the alt boot method (CMD1 with arg 0xFFFF_FFFA) to initiate data transfer
262	1	sigVolt	0x18 for port0 0x33 for port1	Sets the signal voltage for the controller. 0x18 = 1.8V 0x33 = 3.3V
263	1	Reserved	0	Reserved
264	4	Max Bus Freq	0	Max bus frequency in kHz. If 0, the value is determined by reading the CSD register from the card (still maxes out at 25 MHz)
268	4	refClkkHz	0	Module reference clock frequency, in kHz. If 0, the ROM code computes the value.
272	4	respTimeout	40000	The timeout period on initial card read, in milli-seconds, Q3 number format
276	128	Filename	"\tiboot3.bin"	For SD/MMC, boot filename in 16-bit Unicode characters (max 64)
404	4	Mode	0x1144D091	0x1144D091 = file system boot 0x1144C180 = raw image boot
408	4	CardIsInit	0	0 = card not yet initialized 1 = card has been initialized
412	4	Rsvd	0	Reserved
416	4	RawIndex	0	Current active read offset (0 or 1)

Copyright © 2026 Texas Instruments Incorporated

Table 5-58. MMCSD/eMMC Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
420	4	Rsvd	0	Reserved
424	4	Raw Offset 0	0x000000	Raw read offset
428	4	Raw Offset 1	0x400000	Backup raw read offset
432	4	Rsvd	0	Reserved
436	4	Rsvd	0	Reserved

5.6.7 Ethernet Boot Parameter Table

Table 5-59 is shown segmented into four sections:

1. The first section contains information required to configure the device hardware
2. The second section contains information used by the top level Ethernet module to execute the boot
3. The third section contains information for the Ethernet stack code.
4. The fourth section contains information for creating the BOOTP packet (vendor string, ID string and debug string), and holds information returned in the BOOTP response (Default route and file name)

Table 5-59 shows the boot parameter table for Ethernet boot. Must be preceded with the common boot parameters described in Table 5-48.

Table 5-59. Ethernet Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
Hardware Configuration Options				
256	2	Mod Freq	0	Module clock frequency, kHz. If 0, ROM code computes the value.
258	1	Port Num	0	Physical port number
259	1	Interface	From Pins	0 = RGMII with internal delay 1 = RGMII with external delay 2 = RMII
260	1	Init Level	0	0 = Initialize only not enabled modules 1 = Full ethernet sub-system initialization
261	1	Clock out enable	From pins	0x10 = CLKOUT0 enable 0x11 = CLKOUT0 disable
262	1	Clk out freq	From pins	0x20 = CLKOUT0 25 MHz (RGMII) 0x21 = CLKOUT0 50 MHz (RMII)
263	1	RMII Clk In	From pins	0x60 = RMII internal (SoC) clock 0x61 = RMII external clock
264	1	Port Enable	0x01	Bit map. A set bit indicates that the corresponding physical port will be enabled
265	1	Phy Query	From pins	0x30 = speed/duplex determined from RGMII status register 0x31 = MDIO used to query PHY 0x32 = Use fixed speed/duplex values from offset 266/267.
266	1	Speed		0x40 = full speed (1Gbit for RGMII, 100Mbit for RMII) 0x41 = slow speed (100Mbit for RGMII, 10Mbit for RMII)
267	1	Duplex		0x50 = full duplex 0x51 = half duplex
Main Level Boot Control				
268	1	Bootp enable	1	0 = Image information already in this structure 1 = Use BOOTP to get boot image information
269	1	Reserved	0	Reserved
270	2	Bootp Timeout	4000	BOOTP timeout in milli-seconds
272	2	TFTP timeout	1000	TFTP timeout in milli-seconds
274	2	Bootp retries	10	Number of BOOTP retries before fail

Copyright © 2026 Texas Instruments Incorporated

Table 5-59. Ethernet Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
276	2	TFTP retries	10	Number of TFTP retries before fail
278	2	Reserved	0	Reserved
Network Stack Configuration (plus TFTP server ID)				
280	6	MAC Address	From E-fuse	MAC address of the device
286	2	Reserved	0	Reserved
288	4	Device IP	0	IP address of the device. Valid only if BOOTP not enabled
292	4	Net Mask	0	Net mask. Valid only if BOOTP not enabled
296	4	Tftp server IP	0	TFTP server IP. Valid only if BOOTP not enabled
BOOTP send and receive Information				
300	20	Vendor String	"TI K3 Bootp Boot"	BOOTP request vendor string. Valid only if BOOTP not enabled
320	9	Client ID	1-mac-address-0	Client ID. See RFC1700
329	1	ID len	7	Client ID length
330	45	Debug array	SOC ID up to size available	Debug array output
375	1	Debug len	Varies	The number of valid bytes in debug array
376	4	Next hop	0	Next hop IP address. Valid only if bootp not enabled
380	4	Default Route	0	IP default route IP address. Valid only if bootp not enabled
384	128	Boot filename	0	Boot filename. Valid only if bootp not enabled

5.6.8 xSPI/Fast-xSPI Boot Parameter Table

Table 5-60 shows the boot parameter table for xSPI boot. Must be preceded with the common boot parameters described in Table 5-48.

Table 5-60. xSPI/Fast-xSPI Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode on	From Pins	If non-zero, the mode byte will be sent
258	1	Instruct Width	From Pins	Number of pins used to send instructions (1, 8)
259	1	Address Width	From Pins	Number of pins used to send address (1, 8)
260	1	Data Width	From Pins	Number of pins used to received data (1, 8)
261	1	Address Size	24	24 and 32 bits are the valid address sizes
262	1	Mode	0	QSPI clock polarity and phase mode
263	1	CSEL	From Pins	Chip select number (0–3)
264	1	Read Cmd	From Pins	Command used to read read data
265	1	Mode byte	0	Value used for the mode byte (when active)
266	1	Dummy Cycles	From pins	Number of dummy cycles sent after the read command
267	1	clkRecovery	From pins	Clock recovery
268	1	dqsEnable	0	Enable DQS
269	1	ddrEnable	From pins	OSPI DDR mode operation
270	2	Module Freq	0	The QSPI module frequency after PLL enable, in kHz. If 0, ROM code uses the value from the module clock tables.
272	4	Bus Frequency	From pins	The QSPI bus frequency, in kHz
276	4	Delay	0x08080808 or 0x01010101	The chip select read delays. Default value is based on the read command
280	1	SFDP	From Pins	Enables SFDP parser for 1S-1S-1S to 8D-8D-8D switching

Copyright © 2026 Texas Instruments Incorporated

Table 5-60. xSPI/Fast-xSPI Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
282	4	Tap Delay	0xFFFFFFFF	The read tap selection. If 0xFFFFFFFF, the ROM code will scan the taps to find the best delay. The result will then overwrite the value in this table.
286	4	Internal Clk	From pins	0 = external (dqs) 1 = internal
290	4	inDAC	From pins	When 0, XIP mode is used
294	4	Read Index	0	Index to the active read address
298	4	Read Addr 0	0x000000	The initial flash read address
302	4	Read Addr 1	0x400000	Backup read address

5.6.9 USB DFU Boot Parameter Table

USB DFU Boot Parameter Table shows the boot parameter table for USB DFU boot. Must be preceded with the common boot parameters described in Table 5-48.

Table 5-61. USB DFU Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Port	From pins	Physical port number. Always set to 0.
260	4	Base address 0	From pins (port)	Base address of USB subsystem (CMN)
264	4	Base address 1	From pins (port)	Base address of controller
268	4	phyBaseAddress	From pins (port)	Base address of USB PHY module
272	4	modRefClkkHz	varies	Module reference clock, in kHz
276	2	Vendor ID	0x0451	USB vendor ID. Read from control registers.
278	2	Product ID	0x6165	USB product ID. Read from control registers.
280	2	BCD Device	0x200	Binary Coded Decimal device release number
284	4	String Table addr	0x4182A76C	Pointer to the string table in RAM
288	2	Vendor String offset	0	Offset to vendor string in string table
290	2	Prod string offset	32	Offset to product string in string table
292	2	Serial num string offset	64	Offset to serial number string in string table
294	2	Timeout	5000	USB timeout in milliseconds
296	2	Mode	1	1 = DFU ≠1 = MSC Mode 1 = backup DFU, 2 = backup MSC
298	1	Lane reverse	From pins	Set to non-zero for lane reverse
299	1	CoreVoltage	From pins	USB Core Voltage 0 = 0.85V, 1 = 0.75V
300	4	Block Size	4096	DFU Block Size

5.6.10 USB MSC Boot Parameter Table

USB MSC Boot Parameter Table shows the boot parameter table for USB boot. Must be preceded with the common boot parameters described in Table 5-48.

Table 5-62. USB MSC Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Port	From pins	Physical port number. Always set to 0.
260	4	Base address 0	From pins (port)	Base address of USB subsystem (CMN)
264	4	Base address 1	From pins (port)	Base address of controller
268	4	phyBaseAddress	From pins (port)	Base address of USB PHY module
272	4	modRefClkkHz	varies	Module reference clock, in kHz

Copyright © 2026 Texas Instruments Incorporated

Table 5-62. USB MSC Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
276	2	Vendor ID	0x0451	USB vendor ID. Read from control registers.
278	2	Product ID	0x6164	USB product ID. Read from control registers.
280	2	BCD Device	0	Binary Coded Decimal device release number
284	4	String Table addr	0x4182BCA8	Pointer to the string table in RAM
288	2	Vendor String offset	0	Offset to vendor string in string table
290	2	Prod string offset	0	Offset to product string in string table
292	2	Serial num string offset	0	Offset to serial number string in string table
294	2	Timeout	5000	USB timeout in milliseconds
296	2	Mode	1	1 = DFU ≠1 = MSC Mode 1 = backup DFU, 2 = backup MSC
298	1	Lane reverse	From pins	Set to non-zero for lane reverse
299	1	CoreVoltage	From pins	USB Core Voltage 0 = 0.85V, 1 = 0.75V
300	64	FileName	tiboot3.bin	Boot file name

5.6.11 GPMC NOR Boot Parameter Table

Table 5-63 shows the boot parameter table for GPMC NOR boot. Must be preceded with the common boot parameters described in Table 5-48.

Table 5-63. GPMC NOR Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	refClkkHz	0	The module functional clock frequency, in kHz. 0 = ROM code computes the value.
260	4	csSizeMb	64	The size of each chip-select, in MB
264	1	Csel	From pins	The chip-select to use (0-3)
265	1	adMux	From pins	The address/data multiplexing used. 0 = A/D parallel, 1 = A/A/D mux, 2 = A/D mux
266	1	Width	16	Data bus width
267	1	Reserved	0	Reserved
268	4	Read index	0	The currently active read offset (0-1)
272	4	Read offset 0	0x000000	Read address offset 0
276	4	Read offset 1	0x400000	Backup read address offset 1
280	4	Reserved	0	Reserved
284	4	Reserved	0	Reserved

5.6.12 GPMC NAND Boot Parameter Table

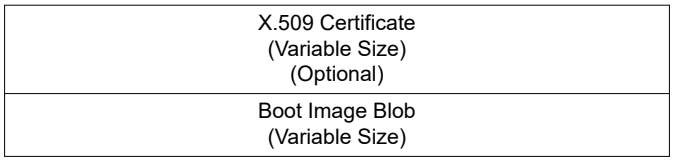
GPMC NAND Boot Parameter Table shows the boot parameter table for GPMC NAND boot. Must be preceded with the common boot parameters described in Table 5-48.

Table 5-64. GPMC NAND Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Ref Clk kHz	From pins	Specifies the module ref clock.
260	4	Page Size	0	Page size in bytes 2048 or 4096
264	1	Chip Select	0	Chip Select
265	1	Ad Mux	0	Address/data multiplexing

Copyright © 2026 Texas Instruments Incorporated

Table 5-64. GPMC NAND Boot Parameter Table (continued)



Byte Offset	Size (bytes)	Name	Default Value	Description
266	1	Data Bus Width	8	Data bus width. Valid values are 8 and 16
267	1	AD rows	0	Number of Row address
268	1	AD columns	0	Number of Column address cycles
269	1	ECC Nibbles	0	Size of BCH remainder in nibbles. 0 if no ECC, 26 for BCH8
270	2	Current Valid Block	0xFFFF	Block number of last known good block
272	2	Pages per Block	0	Number of pages in a block
274	2	Reserved	0	Reserved
276	4	Current Read Index	0	Active read index
280	4	Read Offset[0]	0	Offsets from base of GPMC NAND memory
284	4	Read Offset[1]	0x400000	Offsets from base of GPMC NAND memory

Copyright © 2026 Texas Instruments Incorporated

5.7 Boot Image Format

5.7.1 Overall Structure

The boot image consists of an X.509 Certificate, followed immediately by a boot image blob.

5.7.2 X.509 Certificate

The X.509 certificate is described in RFC5280. Section 4.1 of the specification describes the format.

The X.509 fields relevant to the public boot (taken from RFC5280) are shown below.

```
Certificate  ::=  SEQUENCE  {
        tbsCertificate       TBSCertificate,
        signatureAlgorithm   AlgorithmIdentifier,
        signatureValue       BIT STRING  }
   TBSCertificate  ::=  SEQUENCE  {
        version         [0]  EXPLICIT Version DEFAULT v1,
        serialNumber         CertificateSerialNumber,
        signature            AlgorithmIdentifier,
        issuer               Name,
        validity             Validity,
        subject              Name,
        subjectPublicKeyInfo SubjectPublicKeyInfo,
        issuerUniqueID  [1]  IMPLICIT UniqueIdentifier OPTIONAL,
                             -- If present, version MUST be v2 or v3
        subjectUniqueID [2]  IMPLICIT UniqueIdentifier OPTIONAL,
                             -- If present, version MUST be v2 or v3
        extensions      [3]  EXPLICIT Extensions OPTIONAL
                             -- If present, version MUST be v3
        }
  Extensions  ::=  SEQUENCE SIZE (1..MAX) OF Extension
   Extension  ::=  SEQUENCE  {
        extnID      OBJECT IDENTIFIER,
        critical    BOOLEAN DEFAULT FALSE,
        extnValue   OCTET STRING
                    -- contains the DER encoding of an ASN.1 value
                    -- corresponding to the extension type identified
                    -- by extnID
        }
```

In general, an X.509 certificate contains a public key which has been signed by a private key. The public ROM code does not directly use the keys. In non-secure devices, the public key value is in general a don't care condition. The exception is certificates containing a degenerate RSA public key. GP devices with a degenerate RSA key allow for integrity checking of most (but not all) of the certificate.

The public ROM only needs to extract some of information from the X.509 formatted structure:

- The total size of the X.509 Certificate
- The total size of the boot image

The total size of the X.509 Certificate is determined by reading the length of the sequence containing the certificate. The length of the image is determined by parsing the certificate to find the extension field which holds the image length.

The ROM defines several extensions that are used only by TI for boot. These are placed in the extensions field of the TBS certificate.

5.7.3 Organizational Identifier (OID)

OID (organizational identifier) values are represented as a tree structure. TI has the following node registered:

Copyright © 2026 Texas Instruments Incorporated

1.3.6.1.4.1.294: iso(1), identified-organization(3), dod(6), internet(1), private(4), enterprise(1), Texas Instruments(294)

ROM code adds the following branch after *Texas Instruments*: *device-boot(1)*. The OID values shown in this section are leaves off the device boot branch.

5.7.4 X.509 Extensions Specific to Boot

These values are not defined in any standard, but created by TI for boot.

5.7.4.1 Boot Info (OID 1.3.6.1.4.1.294.1.1)

This extension must be present on all boot images. It is from this extension that the image length is extracted.

```
bootInfo ::=  SEQUENCE {
   cert_type: INTEGER,-- identifies the certificate type
   boot_core:INTEGER,-- identifies the boot core
   core_opts:INTEGER,-- 32 or 64 bit boot core target
   load_addr:OCTET STRING,-- Global address image destination
   image_size:INTEGER,-- Image size in bytes
}
```

Table 5-65. Certificate Type Values

Value	Description
0x0000_0001	Primary boot image
0x0000_0002	Firmware image

Table 5-66. Boot Core Values

Value	Description
0x00	Firmware (M4) image
0x08	M4 certificate
0x10	R5 image
0x20	Reserved

Table 5-67. Core Options Bit Fields

31	2	1	0
Reserved		Split	Mode

Table 5-68. Core Options Field Description

Bits	Field	Value	Description
1	Split	0	Dual MCU set to lockstep (two cores in lockstep)
		1	Dual MCU set to split mode (two independent cores)
0	Mode	0	MCU starts execution in Arm® mode
		1	MCU starts execution in Thumb® mode

5.7.4.2 Image Integrity (OID 1.3.6.1.4.1.294.1.2)

```
imageIntegrity ::= SEQUENCE {
   sha_type:OID,-- Identifies the SHA type
   hash:OCTET STRING-- The SHA of the boot image
}
```

5.7.5 Extended Boot Info Extension

The ROM supports a combined boot image boot flow. In this flow, a boot binary blob has both Secondary bootloader (SBL) and System Firmware (SYS-FW) embedded in the boot image with a single X509 certificate. This method helps with the following situations:

Copyright © 2026 Texas Instruments Incorporated

- Allows ROM to load and run both the bootloader and SYS-FW in parallel without any dependency.
- Optimizes ROM boot time by minimizing different x509 certificate parsing and authentication.

To support this combined boot format, ROM employs a new X509 extension called: ext_boot_info. It supports multiple boot components with a single certificate. It allows up to 5 components as part of this extension:

- Component1: Mandatory and should point to info about SBL binary
- Component2: Optional and if present should point to SYS-FW binary in all device types
- Component3: Optional (Load section to SBL, new certType)
- Component4: Optional (Load section to SYS-FW, new certType)
- Component5:
  - HS-FS and HS-SE non Prime devices. Mandatory and should point to SYS-FW Inner certificate
  - GP and HS-SE Prime devices. Optional (Load Section to SBL or SYS-FW)

This extended boot info extension replaces boot_seq (boot_info) and image_integrity extensions from the previous sections, and these should be exclusive in any given certificate.

ROM supports other extensions, such as sw_rev and debug_info, in both formats.

ROM selects the combined image flow based on the presence of ext_boot_info extension in the certificate and skips boot_seq (boot_info) and image_integrity extensions boot flow.

Having one component in ext_boot_info is same as legacy flow (that is, flow using boot_seq and image_integrity); for two or more components, ROM starts both SBL and SYS-SW, the third and fourth components are loaded by ROM to the allowed loading memory range of SBL and SYS-FW if there is no overlap in load address with executable binary info.

Each of the components can independently specify hash value of the binary, and ROM validates the hash on HS and GP if RSA degenerate key is used for signing.

Additionally, ROM rejects the full image if hash of any single component mismatches.

5.7.5.1 Impact on HS Device

For HS devices, ROM supports encryption of images optionally when specified with the Encryption extenstion.

Encryption - Encryption of the components must be specified with a new extension called ext_boot_enc. This is an optional extension that must be specified only if any of the components are encrypted with a customer key set. Specify a component number followed by encryption extension details for ROM to decrypt the given components. This extension is used only with combined boot image format (that is, using Extended Boot Info Extension).

Prime vs Non-Prime - The main difference between HS prime and non-prime devices is the presence of the SYS-FW Inner certificate. Extended boot info extension supports both prime and non-prime devices. ROM supports SYS-FW binary as Comp#2 in all device types; for HS-SE non-prime and HS-FS devices, the SYS-FW inner certificate is expected as another optional component in #3, 4, or 5.

5.7.5.3 Certificate / Component Types

ROM supports only the following component types; all other component types will be rejected.

- CompType 0x1 for SBL binary - compType = INTEGER:1
- CompType 0x2 for SYS_FW binary - compType = INTEGER:2
- CompType 0x3 for SYS_FW Inner Certificate - compType = INTEGER:3
- CompType 0x11 for SBL Memory load section - compType = INTEGER:17

Primary Image load section, that can be loaded in to SBL allowed memory range:

- CompType 0x12 for SYS_FW Memory load section - compType = INTEGER:18

SYS-FW load section, that can be loaded in to SYS-FW allowed memory range

5.7.5.4 Extended Boot Encryption Info

Extended Boot Encryption Info specifies the imageEncryption extension per component basis. This extension is not applicable for GP or HS-FS devices, and is optional for HS-SE devices if any components in the image are encrypted. In HS-FS and HS-SE non-prime devices, the SYS-FW binary encryption details are part of SYS-FW Inner certificate. This extension is applicable if either SBL, SYS-FW binary in HS-SE prime, or any binary blobs are encrypted in HS-SE devices.

 iterationCnt = INTEGER:2
 salt = FORMAT:HEX,OCT:ccccccccccccccccccaa84f29d6b68d0
```

5.7.5.5 Component Ordering

ROM supports fixed Component ordering for SBL- Binary and SYS-FW Cert and Binary.

For GP and HS-SE Prime devices, Comp#1 should be SBL binary, and Comp#2 should be SYS-FW binary.

For HS-FS and HS-SE non-Prime devices, Comp#1 should be SBL binary, Comp#2 should be SYS-FW Inner Certificate, and Comp#3 should be SYS-FW binary.

5.7.5.6 Memory Load Sections Overlap with Executable Components

Memory load sections for SBL and SYS-FW (CompType 0x11 and 0x12) the destination address and size should not overlap with the corresponding load and execute sections, and should also fall in the allowed memory range by ROM.

5.7.5.7 Device Type and Extended Boot Extension

X509 Extension	Component	GP Device	HS-FS	HS-SE non-prime	HS-SE Prime Device
ext_boot_info	Comp#1	SBL Binary	SBL Binary	SBL Binary	SBL Binary
	Comp#2	SYS-FW binary	SYS-FW binary	SYS-FW binary	SYS-FW binary
	Comp#3	SBL mem load section	SBL mem load section	SBL mem load section	SBL mem load section
	Comp#4	SysFW mem load section	SysFW mem load section	SysFW mem load section	SysFW mem load section
	Comp#5	N/A	SysFW inner certificate	SysFW inner certificate	N/A
ext_enc_info	Comp#1	N/A	N/A1	SBL encryption	SBL encryption
	Comp#2			N/A	SYS FW encryption
	Comp#3			SBL memory load Encryption	SBL memory load encryption
	Comp#4			Sys-FW memory load encryption	Sys-FW memory load encryption
	Comp#5			N/A1	NA

1. SYS-FW encryption in HS-FS and HS-SE (non Prime) are handled in SYS-FW Inner certificate and they are not part of the extended boot info extensions.

5.7.6 Generating X.509 Certificates

X.509 Certificates are generated using OpenSSL and a configuration script to supply values in the extension fields.

5.7.6.1 Key Generation

The SBL must always be signed with a given OpenSSL key - Secure and GP devices. Secure must have encryption and authentication, GP device must only have authentication. The key used for authentication can be random or specific. If a random key is generated and SBL is signed with this,the ROM will copy the SBL image for authentication using memcopy. With this key, ROM code will be directed to use DMA to load the SBL for authentication which saves boot time.

5.7.6.1.1 Degenerate RSA Keys

Degenerate RSA keys are valid RSA keys with the private exponent set to 1. This results in the signature field being equal to the digest, since in RSA:

Copyright © 2026 Texas Instruments Incorporated

$$Signature = digestprivExp \bmod nprivExp \bmod n^{privExp} \quad (1)$$

Where n is the key size. Since the hash used is SHA-512 and the signature is an ASN.1 sequence containing the OID defining which has was used as well as the hash value, the degenerate RSA must have a value of n greater than the maximum digest size. Typically 1024-bit is chosen.

The following sequence is used to generate degenerate RSA keys:

1. Create a random RSA key:

```
openssl genrsa –out key.pm 1024
```

2. Convert to text:

```
openssl rsa –in key.pem –text –noout > key.txt
```

3. Create an asn1 template for the degenerate key called degenerateKey.txt. Simply copy the values for modulus, prime (listed as p in key.txt), prime 2 (listed as q), and coefficient (listed as coeff). Set the public and private key exponents to 1, as well as the values for e1 and e2. See the example below.
4. Convert the template to DER:

```
openssl asn1parse -genconf degenerateKey.txt -out degenerateKey.der
```

5. Sanity check the key:

```
 openssl rsa –in degenerateKey.der –inform der -text -check
```

6. If there are no errors create the degenerate key pem file:

```
openssl rsa –in degenerateKey.der –inform der –outform pem -out degenerateKey.pem
```

An example degenerateKey.txt file is shown.

```
asn1=SEQUENCE:rsa_key
[rsa_key]
version=INTEGER:0
modulus=INTEGER<copied from key.txt>
pubExp=INTEGER:1
privExp=INTEGER:1
p=INTEGER:<copied from key.txt>
q=INTEGER<copied from key.txt>
e1=INTEGER:1
e2=INTEGER:1
coeff=INTEGER<copied from key.txt>
```

Note that when copying the multi-byte fields from key.txt it is necessary to remove the colons, catenate the lines and add a preceding 0x.

5.7.6.2 Configuration Script

An example openssl configuration script is shown below. Not all extensions are required, but all possible are shown.

```
[ req ]
distinguished_name = req_distinguished_name

Icount = INTEGER:1
Salt = FORMAT:HEX,OCT:00112233445566778899aabbccddeeff
[ pllControl ]
pll0_num = INTEGER:0
pll0_cfg = FORMAT:HEX,OCT:00345678900
pll1_num = INTEGER:1
pll0_cfg = FORMAT:HEX,OCT:00345678900
[ debug ]
uid = FORMAT:HEX,OCT:00345678900
type = INTEGER:1
dbgE = INTEGER:0
secDbgEn = INTEGER:0
```

The certificate is then generated using the following openssl command:

```
openssl req -new -x509 -key <private_key_pem_file> -nodes -out <output_X.509_pem_file> -config
<config_file> -sha512
```

If a delegate key is being signed, then add the option -signkey <sign_key_pem_file> to the command above.

5.7.6.3 Image Data

The image data (blob) is considered simply as a byte stream. On devices that are multiple bytes wide the image must be formatted so that all multi-byte fields match the endianness of the device. The R5 will always run in little endian mode.

Copyright © 2026 Texas Instruments Incorporated

5.8 Boot Memory Maps

5.8.1 Memory Layout/MPU

Memory Layout/MPU shows an overview of the MPU configuration. In the R5 MPU, higher numbered regions have priority, therefore in the table, where two regions overlap, the region on the right defines the memory attributes.

5.8.2 Global Memory Addresses Used by ROM Code

The ROM code uses several global memory addresses that are useful for debugging. They are shown in Global Memory Addresses.

Table 5-69. Global Memory Addresses

Group	Address	Size (bytes)	Content
SMS0_HSM_SRAM0_0	0x43c00000	0x7e000	Loadable memory space for SBL
Warning/Error logs	0x43c7e480	0x200	Warning Entries
Warning/Error logs	0x43c7e680	0x200	Severe Entries
Warning/Error logs	0x43c7e880	0x100	Critical Entries
Warning/Error logs	0x43c7eb80	0x14	Circular message buffer
Warning/Error logs	0x43c7eb98	0x50	Boot log context
Trace	0x43c7ebe8	0x18	Boot trace context
Trace	0x43c7ec00	0x400	Boot trace entry buffers
Parameter tables	0x43c7f290	0x4	Parameter tables index for R5 bootloader
Parameter tables	0x43c7f298	0x400	Boot Parameter table for R5 bootloader
Parameter tables	0x43c7f1e0	0xb0	Extended boot data for R5 bootloader

The ROM code version information is a structure shown in Table 5-70

Table 5-70. ROM Code Version

Field	Address	Size (bytes)	Value for PG1
Version Number	0x4182_FF80	0x4	TBD
Version Date	0x4182_FF84	0x8	"TBD"
Device Name	0x4182_FF8C	0xC	"TBD"

6.1 Control Module

Note

Some features may not be available. See *Module Integration* for more information.

6.1.1 Memory Mapped Control Register Modules (CTRL_MMR)

This chapter covers three categories of device level control register modules:

- General-Purpose Control Register Modules
- Pad Configuration Register Modules
- Security Control Register Modules

Each category of module is described in its own section, along with detailed register descriptions for each module.

6.1.2 General Purpose Control Register Modules Overview

There are three General Purpose Control Register Modules on the Device:

- CTRL_MMR0 for the MAIN domain
- WKUP_CTRL_MMR0 for the WKUP domain
- MCU_CTRL_MMR0 shared between the WKUP and MCU domains, with Parity Protection.

6.1.2.1 Description for General Purpose Control Register Module Register Types

The following sub-sections provide summary and description for most of the registers which are part of the CTRL_MMR0, WKUP_CTRL_MMR0 and MCU_CTRL_MMR0 modules memory spaces. The rest of the registers are described in the corresponding chapters where the functionality associated with particular register is covered in more detail.

6.1.2.1.1 Register Partitions

The CTRL_MMR0 memory space is divided into the partitions shown in Table 6-1.

Table 6-1. CTRL_MMR0 Register Partitions

Partition(1)	Description	Proxy0 Offset Range	Proxy1 Offset Range
Partition 0	General configuration and IPC regs	0000h to 1FFFh	2000h to 3FFFh
Partition 1	IP control/status regs	4000h to 5FFFh	6000h to 7FFFh
Partition 2	Clock control/status regs	8000h to 9FFFh	A000h to BFFFh
Partition 6	Power and reset control and status	1 8000h to 1 9FFFh	1 A000h to 1 BFFFh

(1) Not listed partitions are reserved and not used.

The MCU_CTRL_MMR0 memory space is divided into the partitions shown in Table 6-2.

Table 6-2. MCU_CTRL_MMR0 Register Partitions

Partition(1)	Description	Proxy0 Offset Range	Proxy1 Offset Range
Partition 0	General configuration and IPC regs	0000h to 1FFFh	2000h to 3FFFh
Partition 1	IP control/status regs	4000h to 5FFFh	6000h to 7FFFh
Partition 2	Clock control/status regs	8000h to 9FFFh	A000h to BFFFh
Partition 3	BIST control/status regs	C000h to DFFFh	E000h to FFFFh
Partition 4	Verification and test/control status regs	1 0000h to 1 1FFFh	1 2000h to 1 3FFFh
Partition 6	Power and reset control and status	1 8000h to 1 9FFFh	1 A000h to 1 BFFFh

(1) Not listed partitions are reserved and not used.

The WKUP_CTRL_MMR0 memory space is divided into the partitions shown in Table 6-3.

Copyright © 2026 Texas Instruments Incorporated

Table 6-3. WKUP_CTRL_MMR0 Register Partitions

Partition[1]	Description	Proxy0 Offset Range	Proxy1 Offset Range
Partition 0	General configuration and IPC regs	0000h to 1FFFh	2000h to 3FFFh
Partition 1	IP control/status regs	4000h to 5FFFh	6000h to 7FFFh
Partition 2	Clock control/status regs	8000h to 9FFFh	A000h to BFFFh
Partition 3	EFUSE CRC status regs	C000h to DFFFh	E000h to FFFFh
Partition 4	Verification and test control/status regs	1 0000h to 1 1FFFh	1 2000h to 1 3FFFh
Partition 5	DDR frequency Control	1 4000h to 1 5FFFh	1 6000h to 1 7FFFh
Partition 6	Power and reset control and status	1 8000h to 1 9FFFh	1 A000h to 1 BFFFh
Partition 7	Backup Data for Deep Sleep	1 C000h to 1 DFFFh	1 E000h to 1 FFFFh

(1) Not listed partitions are reserved and not used.

6.1.2.1.2 Pad Configuration Registers

The pad configuration registers are used to configure most of the device pads. Each pad configuration register is associated with one pad and has bits as described in *Pad Configuration Register Functional Description*.

Many of the device pads support pad multiplexing. This means that their function can be independently chosen from two or more options. The selection of functions available on each pad is enumerated in table “Pin Multiplexing” of the device-specific Datasheet. The desired function is selected via the MUXMODE field of the associated pad configuration register.

The PADCFG_CTRL0_MMR_CFG0_PADCONFIGx registers control the signal multiplexing of modules in the device MAIN domain.

Note

It is recommended to first configure the PADCONFIG and debounce, as well as the debounce counter values in the SoC MMR, prior to enabling the IP.

6.1.2.1.3 Kick Protection Registers

There are Kick and Proxy registers associated with each CTRL_MMR register partition. This section describes the Kick registers. For information about the Proxy registers see Proxy Addressing Registers.

The Kick registers provide a protection mechanism which prevents spurious writes from changing the values of its registers. The LOCKi_KICK0 and LOCKi_KICK1 registers are used for this purpose. A write is required first to the LOCKi_KICK0[31-1] KEY field and then to the LOCKi_KICK1[31-0] KEY field with exact data values to unlock the protection mechanism. Once released then all registers within Partition "i" having write permissions can be written to. The read only registers are still read only. An indication for unlocked Partition "i" is when the LOCKi_KICK0[0] UNLOCKED bit is set to 1h. When the protection mechanism is locked (indicated by LOCKi_KICK0[0] UNLOCKED = 0h) none of the registers within Partition "i" can be written to. They can only be read..

The key values for all partitions are:

- LOCKi_KICK0 Key: 68EF 3490h
- LOCKi_KICK1 Key: D172 BC5Ah

See *Kick Protection Registers* for Partition Unlock Values.

Writing any other data value to either of these registers locks the protection mechanism and blocks any writes to the registers that reside in Partition "i".

Note

In order to ensure that all registers from all partitions are write protected, software must always re-lock the protection mechanism after completing the register writes.

Copyright © 2026 Texas Instruments Incorporated

6.1.2.1.4 Proxy Addressing Registers

There are Kick and Proxy registers associated with each CTRL_MMR partition. This section describes the Proxy registers. For information about the Kick registers see Kick Protection Registers.

The Proxy registers provide proxy addressing, allowing each of the CTRL_MMR registers to be accessed through two different addresses - Proxy0 and Proxy1. Each partition is 16KB. The first 8KB are for Proxy0 addresses, and the second 8KB are for Proxy1 addresses. The Proxy0 address is intended as the normal read and write access address. The Proxy1 address provides exclusive register write control.

When a bit from the P**x**_CLAIM**y**[31-0] PROXY1_CLAIMED field is set to 1h, a register becomes read-only at its Proxy0 address and may only be written through its Proxy1 address. The Proxy registers themselves may always be read through their Proxy0 address but may only be written through their Proxy1 address.

The **x** (representing the partition) and **y** indices can be calculated through the following equations:

- **x** = INT(HEX2DEC(address_offset)/16384))
- **y** = INT(MOD(HEX2DEC(address_offset),16384)/128)

where:

- INT() rounds down to the nearest integer
- HEX2DEC() converts from hexadecimal to decimal
- MOD() returns the reminder of HEX2DEC(address_offset)/16384

6.1.3 I/O Debounce Control Registers

Some device pads have debounce logic. The following MCU_CTRL_MMR0 registers are used to configure the debounce period as shown in Table 6-4.

Table 6-4. Debounce period

MCU_CTRL_MMR Debounce Register	PADCONFIGx[13-11] DEBOUNCE_SEL setting
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG1	1h
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG2	2h
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG3	3h
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG4	4h
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG5	5h
MCU_CTRL_MMR_CFG0_DBOUNCE_CFG6	6h

Note

The debounce logic is not associated with all signals that can be multiplexed on a pad. Only certain signals can use it.

For information about each signal that has associated debounce logic, see Signal Descriptions in the device Datasheet.

Note

It is recommended to first configure the PADCONFIG and debounce, as well as the debounce counter values in the SoC MMR, prior to enabling the IP.

For information about the PADCONFIGx registers, see *Pad Configuration Registers*.

Table 6-5 shows the debounce period values to load in the MCU_CTRL_MMR_CFG0_DBOUNCE_CFGx[5-0] DB_CFG field.

Copyright © 2026 Texas Instruments Incorporated

Note

The debounce clock selection should happen before the consumer of the debounced signals is enabled as the clock multiplexers for the debounce logic are NOT glitch-free.

Table 6-5. Debounce Period Values

MCU_CTRL_MMR_CFG0_DBOUNCE_CFGx[5:0] DB_CFG Decimal Value	Slow Inputs (32.768kHz (1))	Fast Inputs (25MHz(1))	MCU_CTRL_MMR_CFG0_DBOUNCE_CFGx[5:0] DB_CFG Decimal Value	Slow Inputs (25MHz(1))	Fast Inputs (250MHz(1))
	Delay[ms]	Delay[µs]		Delay[µs]	Delay[ns]
0	bypassed	n/a	32	0.04	4
1	1.95	2.56	33	0.08	8
2	2.93	3.84	34	0.12	12

6.1.4 Security Control Register Modules

The following sections describe the CTRL_MMR0 and PADCFG_CTRL0_CFG0 modules.

6.1.4.1 Security Control Register Modules Overview

There are three Security Control Register Modules on the Device:

- MAIN_SEC_MMR0 for the MAIN domain
- MCU_SEC_MMR0 for the MCU domain
- WKUP_SEC_MMR0 for the WKUP domain

6.2 Power

This chapter describes the power-management architecture implemented in the device.

6.2.1 Power Management Overview

To provide a versatile architecture that supports multiple power-management techniques, the power management framework is built with three levels of resource management: clock, power, and voltage.

These management levels are enforced by defining the managed entities or building blocks of the power management architecture, called the clock, power, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch).

To minimize device power consumption, the clocks can be gated (turned off), or the power to the modules can be switched off, when they are not in use. Independent power and clock control of sections of the device allows for turning on and off specific sections of the device without affecting other sections.

6.2.2 Power Control Modules

The Power Control Modules are divided into two sections, dependent on their functionality - Power Sleep Controller section and Device Manager section.

6.2.2.1 Power Sleep Controller (PSC)

6.2.2.1.1 PSC Architecture

Power Sleep Controller (PSC) is a control component to manage the power domain and module's clock and reset transition. Each PSC module contains multiple power domains, within each power domain, it can contain multiple LPSC. Each LPSC can be used to manage the one or multiple module's reset and clock stop status, see Figure 6-1.

Each power domain has a unique index, starting from number 0. The power domain 0 is a special power domain, which is always on. The status of power domain 0 can't be changed after the device is out of reset.

Each power domain can have one or more Local Power Sleep Control (LPSC). Each LPSC in the same PSC has a unique index value as well. LPSC 0 is special, which user can't change its status. LPSC 0 is always set to be enabled after the device is out of reset.

One LPSC can be used to control the reset and clock status for one or more modules. Some of the LPSC can be used to provide local reset function for the processors, such as A53 and R5 core. LPSC can also be used to manage the clock stop interface for the interfaces between two interconnect IPs. This is mainly used for providing isolation features required by some special features such as security isolation, functional safety isolation or reset isolation between different parts of the SoC.

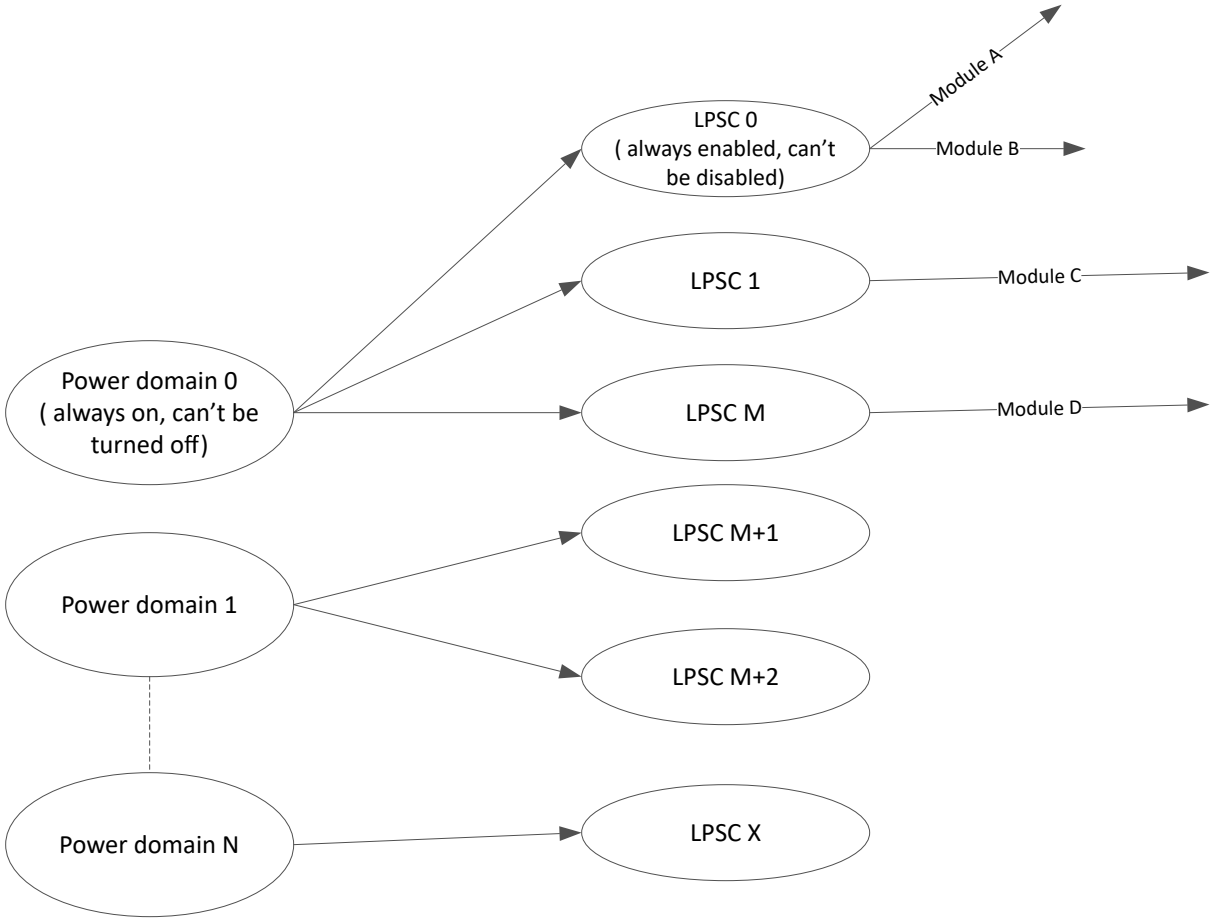

Figure 6-1. PSC Architecture

Note

PSC functions are controlled via Device Manager. For more information how to use Device Manager, see TISCI API available at ti.com.

6.2.2.1.2 PSC0 LPSC Features

6.2.2.1.4 Software Sequence to enable an IP through PSC

In order to enable a module, user needs to program the PSC to put LPSC into enable state. There is dependence between power domain and LPSC and among different LPSC controls.

First of all, in order to enable any LPSC, the power domain which that LPSC belongs needs to be enabled first. The LPSC can't put into any state other than disable if the power domain is not enabled.

Among different LPSC, there is also a special sequence needs to be followed to make sure the device is not getting into undefined state.

Similarly, a special sequence shall be followed to disable the LPSC to prevent device getting into undefined states. Before a power domain can be turned off, all the LPSCs within that power domain shall be disabled first. Normally, user can turn off the power domain to save power. However, it is not necessary to turn off the power domain when all the LPSCs inside that power domain are disabled.

Figure 6-2 shows how to understand the dependent relationship between two LPSCs. In order to enable LPSC_2, LPSC_1 shall be enabled first.

If user wants to disable LPSC_1, LPSC_2 shall be disabled first.

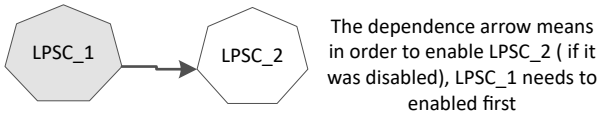

Figure 6-2. LPSC Dependence

Figure 6-3 shows the dependent relationship among all the LPSCs in the device.

6.2.2.2 Device Manager

The device has one Device Manager located in WKUP domain. Device Manager is responsible for entry/exit to low power modes. Also, Device Manager hosts RM/PM (Resource Manager/Power Manager) SYSFW code for providing RM/PM services to HLOS. As part of boot, public ROM is executed over Device Manager.

Device Manager Features

- Single Core Cortex-R5 subsystem
  - ARMv7-R architecture with following extensions

Copyright © 2026 Texas Instruments Incorporated

    - Advanced SIMD extension for integer and floating-point vector operations
    - Vector Floating Point Version 3 (VFPv3)
  - L1 memory architecture
    - 32KB I-cache with 64-bit ECC error checking
    - 32KB D-cache with 64-bit ECC error checking
  - 64Kbyte TCM(L2) with 32-bit ECC error checking
  - 32-bit AXI3 initiator interface for accessing local peripherals
- 1x RTI/WWDT
- 2x Timer
- 1x UART
- 1x I2C
- Wake-up logic
- Public ROM
- RTC digital
- VTM
- LFOSC

Note

PSC functions are controlled via Device Manager. For more information how to use Device Manager, see TISCI API available at ti.com.

6.2.3 Power Management Techniques

The following section describes the power management techniques supported by the processor.

6.2.3.1 Dynamic Frequency Scaling (DFS)

DFS is a power management technique where the operating frequency is dynamically scaled across device Operating Performance Points (OPP). An OPP is a voltage/frequency pair that defines a specific power consumption operating condition (specific power state.) For each OPP, software controls clock frequency in order to adjust the performance and power to the optimum point. The Device supports DFS for Cortex-A53 only.

6.2.3.2 OPP Low

The device supports lower bus frequency operation as OPP Low. The OPP Low must be configured at boot time. In OPP Low, the main CBASS clock frequency is reduced in half in order to lower active power consumption with reduced performance. The performance of some peripheral modules is limited or not available in this operating condition.

Refer to the device datasheet to determine the supported features and the clock frequency of cores, modules, and peripheral I/Os in OPP Low.

6.2.4 Power Management Subsystems

This section provides an overview of how three Power blocks work together; the three blocks are: Power On Reset module (POR), Power OK module (POK), and the POK Reset Generator – Ping-Pong module (PRG_PP) and a PRG without Ping-Pong (PRG).

6.2.4.1 Power Subsystems Overview

6.2.4.1.1 POK Overview

POK modules are responsible for accurately detecting average voltage levels.

Two types of POK modules are implemented in this family of devices - POK and POK_SA.

POK module is capable of monitoring a range of supplies and indicating a failure within the programmable upper and lower threshold limits for the supply being monitored. POKs are used to monitor 3.3 V, 1.8 V and core supply levels with programmable threshold levels.

Figure 6-4 shows the concept of the POK. It is a comparator with a fixed 0.45V and the voltage to be monitored. The voltage-to-be-monitored is defined based upon a CTRL register (see *POK Related Registers*) and the silicon hook-up of the POK. The POK has three possible input voltage ports – VDD_MON3P3, VDD_MON1P8, and VDD_MON. The effect of the CTRL register depends upon which of these three ports is selected (defined in Table 6-12); for example, a threshold value of 0x28 in the threshold register would create a different threshold voltage depending upon:

- How the POK was hooked-up (i.e. VDD_MON3P3, VDD_MON1P8, or VDD_MON) see *POK Modules and Monitored Voltages*.
- Whether the POK is selected for undervoltage detection or overvoltage detection as determined by bit 7 in the POK CTRL register (e.g. CTRL_MMR_POR_VDDR_MCU_UV_CTRL)

The POK output triggers high (i.e. indicating a fail condition) when:

- Under-voltage: the monitored voltage (divided based upon CTRL registers) is less than 0.45V. The CTRL register tables translate the input voltage back to a monitored voltage level (see Table 6-12). If the monitored voltage falls below the trip point, the POK outputs HIGH, (i.e. FAIL).
- Over-voltage: the monitored voltage (divided based upon CTRL registers) is greater than 0.45V. The CTRL register tables translate the input voltage back to a monitored voltage level (see Table 6-12). If the monitored voltage rises above the trip point, the POK outputs HIGH, (i.e. FAIL).

When the monitored voltage threshold is changed, the new threshold settles within 9us.

Figure 6-4 also shows a mux on the output of the comparator. The mux is configured based upon the selection of under-voltage or over-voltage and is used to maintain the proper polarity of the fail signature.

Note

POK_SA (used only on VMON1_ER_VSYS) directly compares the monitored voltage to 0.45V.

Two other features of the POK diagram (i.e. Figure 6-4 and Figure 6-5) need some explanation:

- The comparator can be enabled or disabled individually; note, that once enabled, the comparator output is continuous (though as shown below in is sampled and filtered). The comparator enable settling time is 15us.
- Hysteresis is applied to the comparator input. In general, it is expected that the monitored voltage is far away from the reference and that the hysteresis is moot.

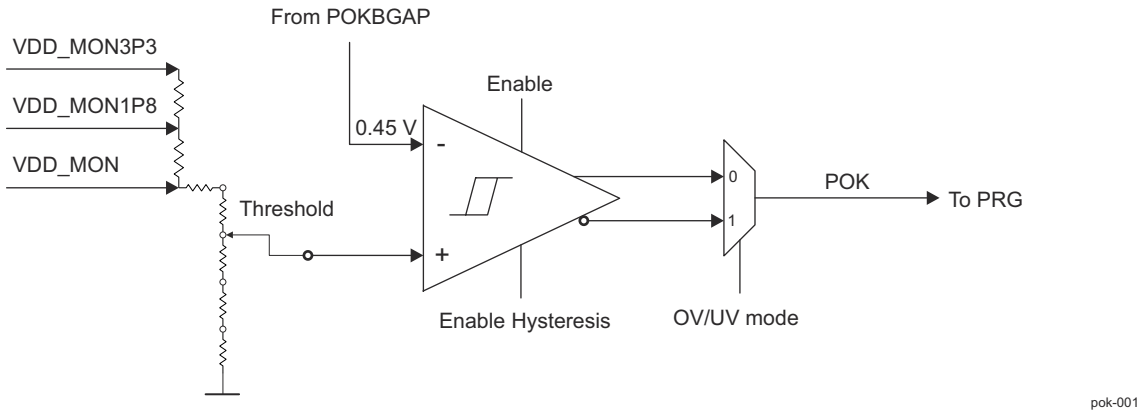

Figure 6-4. POK Block Diagram

Table 6-8. POK Programmable Features

Programmable Feature	Bitfield in the POK Dedicated Register
POK hysteresis enable	[31] HYST_EN
POK over- or under-voltage detection mode	[7] OVER_VOLT_DET
POK trim bits for voltage comparator threshold	[6-0] POK_TRIM

Like the POK, the POK_SA is a comparator with 0.45V reference; however, voltage division must occur in hardware on the PCB before the monitored voltage is applied to VMON1_ER_VSYS.

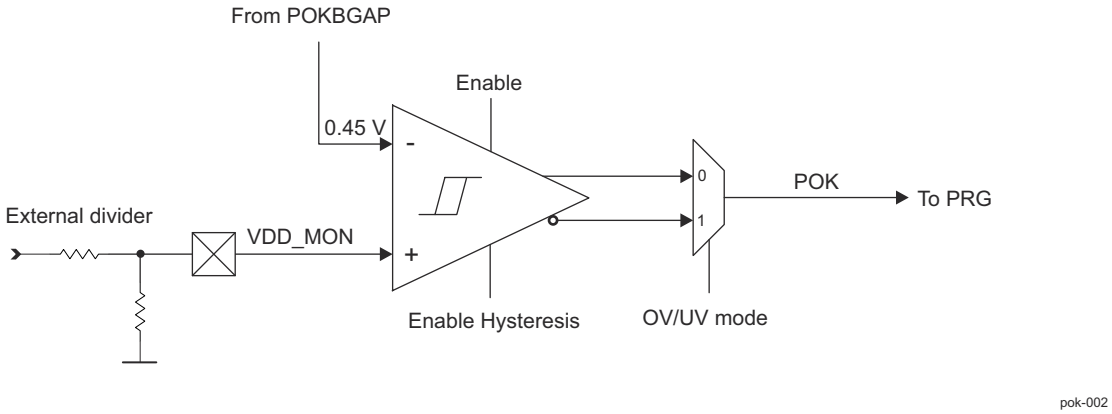

Figure 6-5. POK_SA Block Diagram

Table 6-9. POK_SA Programmable Features

Programmable Feature	Bitfield in the POK Dedicated Register
POK hysteresis enable	[31] HYST_EN
POK over- or under-voltage detection mode	[0] OVER_VOLT_DET

Note

POK configuration is not designed to find and report an instantaneous dip / rise in the voltage.

6.2.4.1.1.1 Configuration Registers

Configuration registers needed for POK (Supervisor Module) are given in Table 6-13. For each POK there is one comparator that is controlled through the registers. These registers decide the functionality of the POK Comparator. It decides if it is UV/OV mode and also the threshold voltages.

Comparator threshold levels and corresponding configuration register settings are given in the following tables:

- POK_CORE: Table 6-14
- POK_1P8: Table 6-15
- POK_3P3: Table 6-16

Table 6-13. POK Configuration Registers

6.2.4.1.2 PRG / PRG_PP Overview

The POKs are both controlled by and send their output back through the PRG(_PP) module; the PRG(_PP) module, all of which reside in the WKUP domain.

1. Controls the POKs – enable / disable, over-volt / under-volt / ping-pong
2. Samples the continuous output
3. Filters the output

Copyright © 2026 Texas Instruments Incorporated

Each POK is controlled, sampled, and filtered by a specific PRG(_PP) (see *POK Modules and Monitored Voltages*) and the control register within that PRG(_PP) is where the POKs are controlled (e.g. CTRL_MMR_PRG_POR_CTRL).

1. Control of the POKs: The POK threshold voltage and hysteresis enable are set in CTRL registers defined in *POK Related Registers*. The PRG(_PP) controls how these POKs are enabled / disabled and how the threshold are applied:
   - Enable / Disable has both;
     a. A global control –POK_EN_SEL (e.g. CTRL_MMR_PRG_PP_MCU_CTRL[15]). POK_EN_SEL disables all controlled POKs when 0 and gives control to the per-POK enable when 1.
     b. A per-POK enable (e.g. CTRL_MMR_PRG_PP_MCU_CTRL[1]. POK_VDDR_MCU_EN)

     To enable a given POK, both levels of enable are required to be set.
   - The options on how thresholds are applied to the POK is the key difference between the PRG_PP and PRG modules. The PRG_PP module will be described in this bullet and then the restriction imposed by the PRG module will be addressed. The PRG_PP can be configured in any of three modes, shown in Table 6-17.
   - Sampling the POKs: The POKs are sampled by a divided-down CLK_12M_RC (WKUP_RC_OSC_12M from the internal RC oscillator). The sampling clock is nominally 12.5MHz (though because it is an RC-generated clock, the frequency is not precise). This input clock is divided by 16 so that sampling records the POK output on the rising edge every ~1.25us.
   - Filtering the output: The output is filtered by means of the DEGLITCH_SEL bitfield (e.g. CTRL_MMR_PRG_PP_MCU_CTRL[17:16]). The bitfield allows the user to select a window of 5us, 10us, 15us or 20us; the POK must be in a FAIL state for ALL samples within the filter window in order for the POK output from the PRG to be seen as FAIL.

Note

DEGLITCH_SEL defines number of samples; the precise duration of the filter is not well controlled.
- For example, the 5us deglitch window samples the POK 4 times and ALL 4 samples must FAIL before the PRG propagates FAIL to the system.
- For example, the 20us deglitch window samples the POK 16 times and ALL 16 samples must FAIL before the PRG propagates FAIL to the system.

Note

PRG in POR does not support ping-pong.

Table 6-17. PRG_PP Modes

Mode:	Example Register / Bitfield
Each POK can be configured to apply the undervoltage threshold continuously. 1. OV_SEL is cleared; the threshold voltage is taken from *UV_CTRL 2. POK_PP_EN is cleared	CTRL_MMR_ POK_VDDR_MCU_UV_CTRL CTRL_MMR_PRG_PP_MCU_CTRL[9]. POK_VDDR_MCU_OV_SEL = 0 CTRL_MMR_PRG_PP_MCU_CTRL[19] POK_PP_EN = 0
Each POK can be configured to apply the overvoltage threshold continuously. 1. OV_SEL is set; the threshold voltage is taken from *OV_CTRL 2. POK_PP_EN is cleared	CTRL_MMR_ POK_VDDR_MCU_OV_CTRL CTRL_MMR_PRG_PP_MCU_CTRL[9]. POK_VDDR_MCU_OV_SEL = 1 CTRL_MMR_PRG_PP_MCU_CTRL[19] = 0

Table 6-17. PRG_PP Modes (continued)

Mode:	Example Register / Bitfield
All POK can be configured to apply the undervoltage threshold then the overvoltage threshold iteratively (ping-pong) 1. All OV_SEL are cleared 2. POK_PP_EN is set; the threshold voltage is taken from *UV_CTRL in the UV phase; the threshold voltage is taken from *OV_CTRL in the OV phase	CTRL_MMR_ POK_VDDR_MCU_UV_CTRL CTRL_MMR_ POK_VDDR_MCU_OV_CTRL CTRL_MMR_PRG_PP_MCU_CTRL[10:8] = 000b CTRL_MMR_PRG_PP_MCU_CTRL[19] = 1

6.2.4.1.3 POR Overview

The POR module should be viewed as a transparent wrapper to the PRG / POKs instantiated within *except* for the following points:

- The bandgap which supplies all POKs is within the POR. The bandgap generates an untrimmed voltage / current after MCU_PORz is released. In order to apply the device-specific trim to the bandgap, the user must set CTRL_MMR_POR_CTRL[7]. TRIM_SEL. The bandgap requires a 100us settling time (during which POK / PRG configuration may occur).
- The device-specific bandgap trim is stored in CTRL_MMR_POR_BANDGAP_CTRL and it is recommended to not modify this trim value.
- The threshold controls for the POKs within the POR are also enabled when TRIM_SEL is set.
- As noted above, the PRG within the POR does not support ping-pong application of thresholds; these POKs monitor a fixed threshold.

6.2.4.1.4 POK / PRG(_PP) /POR Overview

Summarizing this section: The POK block diagram shows a comparator with:

Element of POK	Point of control
resistor divider	*POK*_CTRL registers
hysteresis enable	
comparator enable	*PRG*_CTRL
mux on the output	*POK*_CTRL registers

The output of the POR / PRG_PP / POK voltage monitoring goes to the ESM. Each undervoltage / overvoltage condition has its own bit in the ESM, and the ESM can be programmed to respond to these bits as an interrupt and/or to generate an external signal to the system.

6.2.4.1.5 Timing

As noted in above, there are three timings that are critical:

- 100-us bandgap settling
- 15-us POK enable settling can be concurrent to 100-us bandgap settling
- 9-us POK threshold settling which can be concurrent to both the 100-us bandgap settling and the 15us POK settling

Figure 6-6 shows the sampled POK output to the ESM when the POK threshold is ping-ponged.

- A POK settling time of 1.25-us clocks is fixed in the design; this provides settling for the new threshold voltage when the POK is ping-ponged
- The deglitch (filter) time can be chosen as {4, 8, 12, 16} 1.25-us clock cycles.
- One 1.25-us clock period provides an update window to the ESM.

In this case, the ESM sees an update of the POK threshold every (+ {4, 8,12,16} + 1) × 1.25[µs]. Since the ESM sees an update of a threshold every ~15us to every ~-us, the UV and OV flags are individually being updated every ~-us to every -us.

Copyright © 2026 Texas Instruments Incorporated

In the case where the PRG does not ping-pong, a fixed threshold is applied. The deglitch (filter) time can be chosen as {4, 8, 12, 16} 1.25-us clock cycles. The filter is a sliding window that evaluates the filtered output every 1.25-us based upon the last *n* samples (n = {4, 8, 12, 16}). In this case, the ESM sees an update of the POK threshold every 1.25 us.

The POKs are sampled by a divided-down CLK_12M_RC (WKUP_RC_OSC_12M from Section 5.4.4.1.2). The sampling clock is nominally 12.5 MHz (though because it is an RC-generated clock, the frequency is not precise). This input clock is divided by 16 so that sampling records the POK output on the rising edge every ~1.25 us.

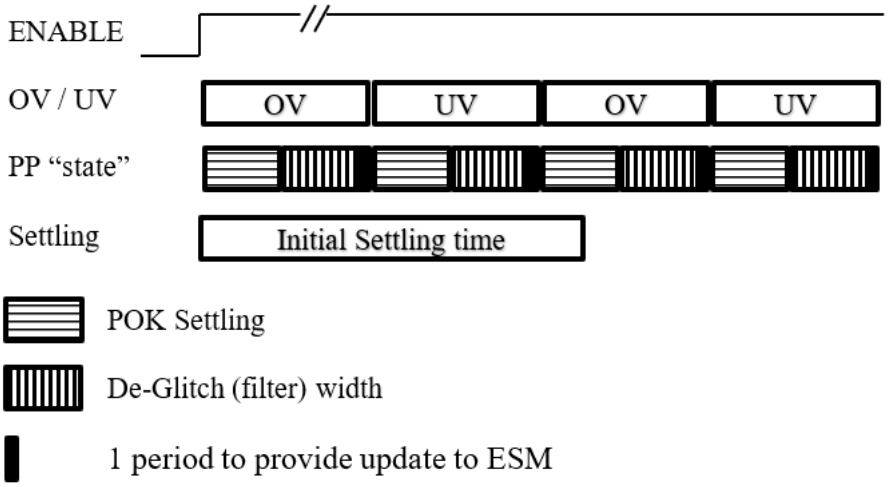

Figure 6-6. Timing for POK with Ping-Pong and Deglitch of 5us

6.2.4.1.6 Restrictions

1. POK monitoring occurs within the initial POK settling (from enable). It is therefore required that the initial state of the POK after enable should be discarded; further, the ESM should be configured for its system response after the initial results during the settling time are discarded.
2. Within a PRG, all POKs must ping-pong or all monitor a static threshold
3. It is not advised to change the threshold from UV to OV while the POK is enabled

6.2.4.2 Power System Modules

6.2.4.2.1 Power OK (POK) Modules

Table 6-18 shows POK modules allocation within device domains.

Table 6-18. POK Allocation Within Device Domains

Table 6-18. POK Allocation Within Device Domains (continued)

IPOK_CAP_VDDS_MCU_GEN	✓	-	-
IPOK_VDDA_PMIC_IN	✓	-	-

Note

All POK modules are located in the WKUP domain regardless of the voltage domain they monitor.

Note

In this family of devices, the Power-on-reset (POR) module is used only for voltage monitoring, as three additional POK modules. For more information about POK functionality in POR module - voltage being monitored and type (under voltage or over voltage), see *Power on Reset (POR) Module*.

Table 6-19. Possible Monitored Voltages

POK Type	Monitored Voltage Values
POK	3.3 V, 1.8 V, or core voltages
POK_SA	0.45 V (allows for external resistor divider for a wide range of scaled voltages)

Figure 6-7 and Figure 6-8 are block diagrams of the two POK types.

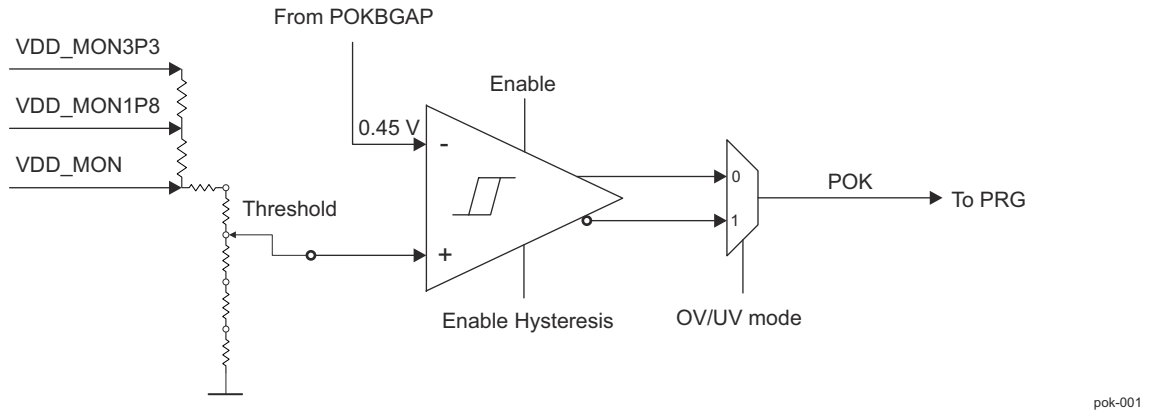

Figure 6-7. POK Block Diagram

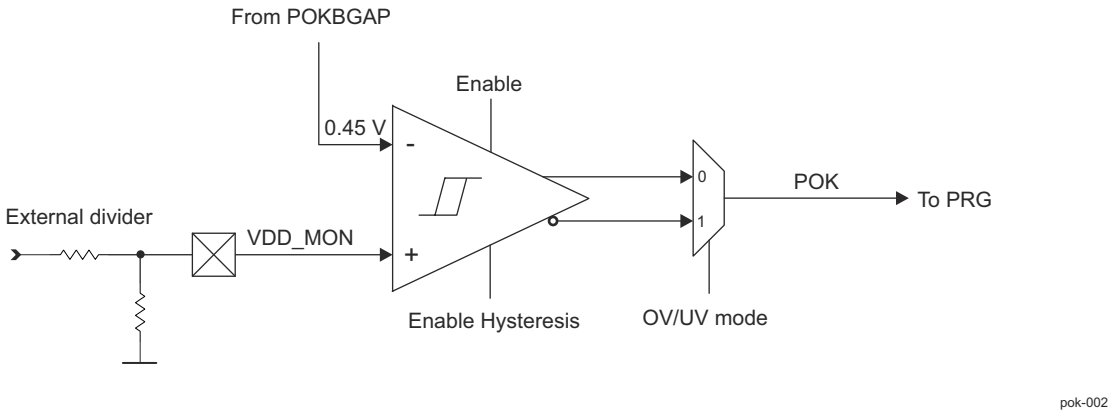

Figure 6-8. POK_SA Block Diagram

Vref for both POK and POK_SA types in Figure 6-7 and Figure 6-8 is supplied from POR module.

6.2.4.2.1.1 POK Programming Model

Table 6-21 and Table 6-22 show the programmable features for the POK modules based on the block diagrams shown in Figure 6-7 and Figure 6-8. Furthermore, each POK module has its own dedicated register to set its programmable features. Table 6-23 lists those registers.

Table 6-21. POK Programmable Features

Programmable Feature	Bitfield in the POK Dedicated Register
POK hysteresis enable	[31] HYST_EN
POK over- or under-voltage detection mode	[7] OVER_VOLT_DET
POK trim bits for voltage comparator threshold	[6-0] POK_TRIM

Table 6-22. POK_SA Programmable Features

Programmable Feature	Bitfield in the POK Dedicated Register
POK hysteresis enable	[31] HYST_EN
POK over- or under-voltage detection mode	[0] OVER_VOLT_DET

PRG controls for the POKs include:

- ping-pong operation enable
- de-glitch period select
- POK OV or UV operation select (if not in ping-pong mode)
- POK enable

See the corresponding PRG control register in Table 6-23.

6.2.4.2.3 Power Glitch Detect (PGD) Modules

A Power Glitch Detect (PGD) circuit is used to detect short duration “glitches” on the core and MPU power supplies. The PGD provides a low output when no glitch is detected and a high output when a glitch is detected.

Figure 6-10 shows the PGD block diagram.

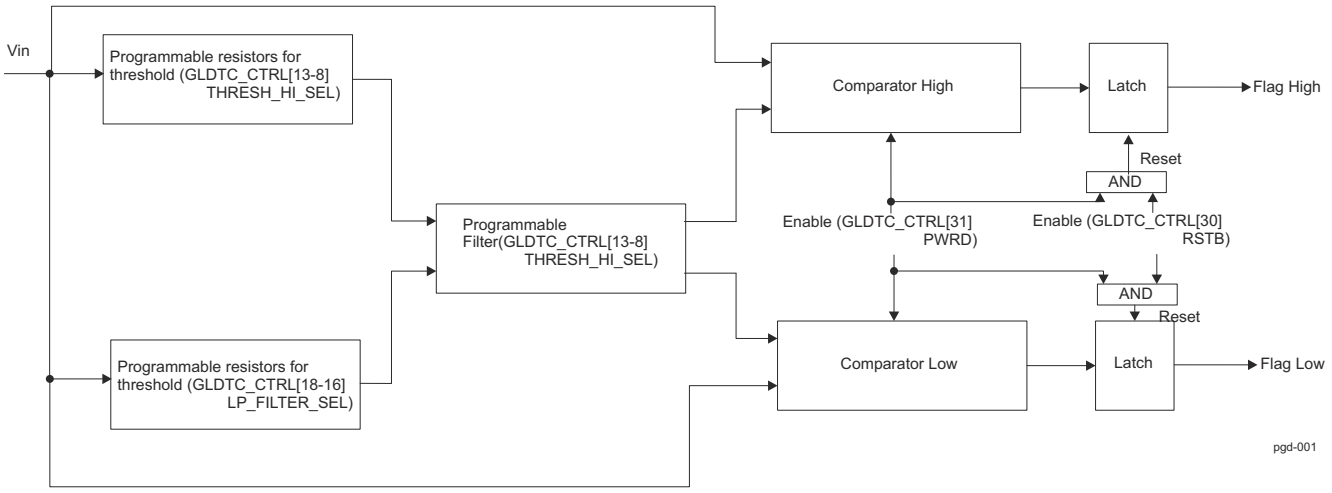

Figure 6-10. PGD Block Diagram

Table 6-26 summarize the PGD integration.

Table 6-26. PGD Integration Summary

Module Instance	Monitored Voltage	PGD Control/Status Registers
IPGD_VDD_MCU_CORE	VDD_MCU	CTRL_MMR_VDD_MCU_GLDTC_CTRL
		CTRL_MMR_VDD_MCU_GLDTC_STAT

6.2.4.2.4 Voltage and Thermal Manager (VTM)

6.2.4.2.4.1 VTM Overview

This section describes the Voltage and Thermal Manager (VTM) module in the device.

In the same way that PRGs control and provide output from the POKs, the VTM controls and outputs signals from temperature sensors that are spread around the die.VTM provides the control, status as well as interrupt and event generation related to integrated temperature sensors and thermal events programed by the user. VTM also contains a set of memory mapped registers that store device-specific operating voltages (AVSVNOM) set during device testing. These values may be used for the system AVS software to adjust operating voltages for the device to achieve optimal operating power.

The device supports one VTM module - WKUP_VTM0. Table 6-27 shows VTM module allocation within device domains.

Table 6-27. VTM Module Allocation within Device Domains

Module Instance	Domain		
	WKUP	MCU	MAIN
WKUP_VTM0	✓	-	-

6.2.4.2.4.1.1 VTM Features

VTM module supports the following features:

- AVS-Class0 only
- Supports up to 8 temperature monitors
- Programming of temperature-crossing thresholds
- Signals when programed thresholds are exceeded - up to 3 alerts:
  - Three full reference 10-bit temperature threshold points, THPT1, THPT2 and THPT0.
- Supports up to 8 temperature monitors
- Allows resolution of 0.5°C for temperature reading and threshold point temperature alert/interrupt generation.
- Supports PMIC/LDO set-up with Class-0 VDD-VID settings
- Support of tentative customization of OPP voltage per device (in support of multiple OPPs)
- AVS-voltage or thermal management for up to 8 voltage domains
- Maximum temperature alert
- Supports one shot sampling mode and continuous monitoring mode for the sensors

Note

The VTM of this family of devices has only 7 temperature sensors and 3 voltage domains.

The ‘j’ notation in the following registers increment from 0 to 6 to map to the 7 temp sensors on the SoC. (Refer to Table 6-32):

- TMPSENS_CTRL_j
- TMPSENS_STAT_j
- TMPSENS_TH_j
- TMPSENS_TH2_j

The ‘j’ notation in the following registers increment from 0 to 2 to map to the 3 voltage domains on the SoC (refer to Table 6-28):

- VD_EVT_SEL_SET_j
- VD_EVT_SEL_CLR_j

6.2.4.2.4.1.2 VTM Not Supported Features

- No support for AVS-Class0 with temperature compensation (AVS0 + TC)
- No integrated I2C inside VTM
- No direct hardware triggering of I2C transactions by VTM

Copyright © 2026 Texas Instruments Incorporated

- No support for voltage and thermal management of IO voltage domains
- No oversampling of the temperature reading
- No support for eFuse defaults of all register values

Copyright © 2026 Texas Instruments Incorporated

6.2.4.2.4.2 VTM Functional Description

In the same way that PRGs control and provide output from the POKs, the VTM controls and outputs signals from several temperature sensors that are spread around the die. The VTM provides three interrupts / ESM inputs to the system as well as a warm reset.

The temperature sensor is configured to run off a clock frequency between 1.15MHz and 1.25MHz. The frequency is obtained by dividing-down HFOSC0 or the internal RC clock; the expected usage is that the temperature sensors use HFOSC0 (TSENS_CLK_DIV is the divider). The temperature sensor will sample the temperature on a period defined by VTM_VTM_SAMPLE_CTRL.

When the temperature sensor is enabled, it senses the temperature and reports the temperature as a 10-bit value.

- The raw 10-bit value is reported in VTM_VTM_TMPSENS_STAT_j;
- It is also compared to pre-defined thresholds (each temperature sensor has its own set thresholds set in VTM_VTM_TMPSENS_TH_j and VTM_VTM_TMPSENS_TH2_j) ;
- It is also compared to a pre-defined global threshold set in VTM_VTM_MISC_CTRL2.

Each of these comparisons can be individually enabled (VTM_VTM_TMPSENS_CTRL_j and VTM_VTM_TMPSENS_CTRL_j within mmr_vbusp_cfg2). Additionally, each temperature sensor has status bits for these comparator outputs in VTM_VTM_TMPSENS_STAT_j.

The comparator functionality that drives the interrupts and warm reset work only when the sensor is configured for continuous mode; continuous operation becomes a de facto requirement (and is set in VTM_VTM_TMPSENS_CTRL_j[4].CONT within mmr_vbusp_cfg2 – that is, the mode is set for *each* temperature sensor).

Interrupts / ESM inputs:

The comparator thresholds shall always configured so that TH2 > TH1 > TH0. The concept is:

- TH1 is configured as an early alarm to indicate that the temperature is greater than the threshold defined in VTM_VTM_TMPSENS_TH_j[25-16] TH1_VAL.
- TH2 is configured as a warning to indicate that the temperature is greater than the threshold defined in VTM_VTM_TMPSENS_TH2_j[9-0] TH2_VAL. The concept is that TH1 indicates that the processor is getting hot; TH2 demands immediate attention.
- TH0 is configured to trigger when the sensor detects the temperature less than the threshold defined in VTM_VTM_TMPSENS_TH_j[9-0] TH0_VAL. This interrupt indicates that the thermal mitigations can be relaxed because the temperature has fallen below the original TH1 level.

LT_TH0_INT, if enabled, will get triggered always when the temperature being read is less than TH0, regardless of whether TH1 interrupt and TH2 interrupt are enabled or have ever been triggered. Therefore if TH0 interrupt is generated, then firmware/software is responsible to enable the TH0 interrupt only as part of the interrupt service routine of TH1 and TH2. Otherwise it will keep triggering when is not needed.

Warm Reset input:

Similar to the interrupts / ESM inputs, the warm reset generation is triggered off a threshold defined in VTM_VTM_MISC_CTRL2[9-0] MAXT_OUTRG_ALERT_THR. The reset will be released when the compared temperature drops below VTM_VTM_MISC_CTRL2[25-16] MAXT_OUTRG_ALERT_THR0.

VTM muxing of the temperature comparisons:

The VTM is configured by voltage domains. At this level, all the interrupt / ESM inputs from each temperature sensor can be enabled or disabled; as an example, the comparator outputs from temperature sensor 0 can be ignored in voltage domain 0. The enable is configured with the VTM_VTM_VD_EVT_SEL_SET_j and VTM_VTM_VD_EVT_SEL_CLR_j registers. At the voltage domain-level, the enabled comparator results are combined by interrupt / ESM signal. The combined comparator result can be observed in VTM_VTM_VD_EVT_STAT_j. As is shown in the following table, j increments over voltage domains for these

Copyright © 2026 Texas Instruments Incorporated

registers (see Table 6-28). The registers TMPSENS_*_j map to the individual temp sensors, as shown in *VTM TEMPSENSOR Register Groups Mapping to Voltage Domains*.

Table 6-28. VTM Voltage Domains

Register Group	Voltage Domain
WKUP_VTM_*_VD_*_0	VDD_MCU
WKUP_VTM_*_VD_*_1	VDD_CORE
WKUP_VTM_*_VD_*_2	VDD_CPU_AVS
others	Unused

After the temperature sensors are combined at a voltage domain level, the outputs from each voltage domain are enabled at the top level of the VTM with VTM_VTM_GT_TH2_INT_EN_SET / VTM_VTM_GT_TH2_INT_EN_CLR, VTM_VTM_GT_TH1_INT_EN_SET / VTM_VTM_GT_TH1_INT_EN_CLR, and VTM_VTM_LT_TH0_INT_EN_SET / VTM_VTM_LT_TH0_INT_EN_CLR. At this top level of the VTM, the status of these signals is checked and cleared with VTM_VTM_GT_TH2_INT_RAW_STAT_SET / VTM_VTM_GT_TH2_INT_EN_STAT_CLR, VTM_VTM_GT_TH1_INT_RAW_STAT_SET / VTM_VTM_GT_TH1_INT_EN_STAT_CLR, and VTM_VTM_LT_TH0_INT_RAW_STAT_SET / VTM_VTM_LT_TH0_INT_EN_STAT_CLR.

VTM control of the global comparison that generates a warm reset:

The global comparison that generates a warm rest is enabled at each temperatures sensor with WKUP_VTM_TMPSENS_CTRL_j[11] within mmr_vbusp_cfg2. Additionally, there is a global enable for this signal in WKUP_VTM_MISC_CTRL[0].

AVS voltage definition:

The VTM also contains the Adaptive Voltage Scaling (AVS) voltage for the VDD_CPU domain. Since the VDD_CPU domain is defined by voltage domain 2, the registers of interest are VTM_VTM_VD_DEVINFO_2 and VTM_VTM_VD_OPPVID_2. If VTM_VTM_VD_DEVINFO_2[12] AVS0_SUP is set, then the device should set the voltage defined in VTM_VTM_VD_OPPVID_2[15-8] OPP_1. The voltage is encoded according to the table below:

6.2.4.2.4.2.1 VTM Temperature Status and Thermal Management

VTM module provides temperature reading and interrupt/alert information for thermal management.

6.2.4.2.4.2.1.1 10-bit Temperature Values Versus Temperature

Table 6-30 shows a table lookup method for translating code to temperature from temperature monitors which correspond to the temperature measured read from the VTM0_VTM_TMPSENS_STAT_J [9-0] DATA_OUT bitfields. Table 6-30 also provides the values for the temperatures coded in VTM0_VTM_MISC_CTRL2 [25-16] MAXT_OUTRG_ALERT_THR0 and VTM0_VTM_MISC_CTRL2 [9-0] MAXT_OUTRG_ALERT_THR thresholds.

Table 6-30. Temperature Translation Table

Parameter Type	Value								
Temperature [°C] (rounded)	-40	-25	0	25	50	75	100	125	150
Temperature [°C] (unrounded)	-40.03	-24.95	0.01	25.02	49.94	75.03	100.02	124.97	150.00
DATA_OUT Code	28	77	164	260	366	485	620	773	949

Table 6-31 shows a table that gives coefficients of polynomial to calculate code or temperature. The equation to calculate code or temperature is:

$y = a4 \times x^4 + a3 \times x^3 + a2 \times x^2 + a1 \times x + a0$

Table 6-31. Equation Method to Calculate Code or Temperature

Function	Unit	Coefficient				
		a4	a3	a2	a1	a0
Code = f(Temperature)	Decimal value of code	4.9847E-08	1.6972E-05	6.8759E-03	3.6509E+00	1.6407E+02
Temperature = f(Code)	°C	-9.2627E-12	6.0373E-08	-1.7058E-04	3.2512E-01	-4.9002E+01

6.2.4.2.4.2.2 VTM Temperature Driven Alerts and Interrupts

All 3 alerts from the 7 (5 shown in sketch) temperature monitors are available as inputs of the mask and alert merging logic block of each voltage domain, such that the temperature monitors that are relevant to each voltage domain can be selected as the contributors to the generation of the 3 combined interrupts in each voltage domain (5 shown in sketch; 3). This logic is presented in Figure 6-11. The THERM_MAXTEMP_OUTRANGE_ALERT is not shown in this figure. Notice that the same temperature sensor can contribute to more than one voltage domain and each voltage domain can have multiple sensors contributing to the interrupt generation in that VD, see VTM_CFG1_VD_EVT_SET_j and VTM_CFG1_VD_EVT_CLR_j registers.

Copyright © 2026 Texas Instruments Incorporated

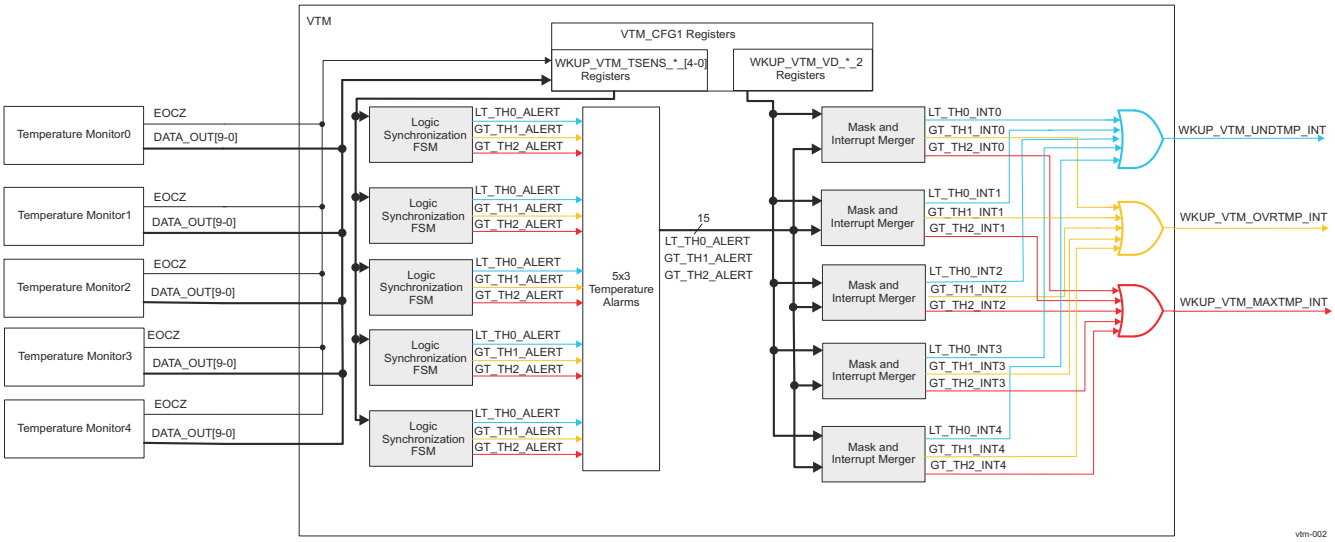

Figure 6-11. VTM Alert and Interrupt Generation

Note

The interrupts are only active when the sensor is in continuous mode. A one-shot sampling of the sensor will not trigger any interrupts.

Table 6-32 presents the connection of VTM TEMPSENSOR registers groups to voltage domains.

Table 6-32. VTM TEMPSENSOR Register Groups Mapping to Voltage Domains

Register Group	Voltage Domain
WKUP_VTM_TMPSENS_*_0	Near MCU_R5FSS in VDD_MCU
WKUP_VTM_TMPSENS_*_1	On VDD_MCU / VDD_CPU boundary near A72 (in VDD_MCU)
WKUP_VTM_TMPSENS_*_2	Near GPU in VDD_CORE
WKUP_VTM_TMPSENS_*_3	On VDD_CORE / VDD_CPU boundary near C7x / MMA (in VDD_CORE)
WKUP_VTM_TMPSENS_*_4	On VDD_CORE / VDD_CPU boundary near A72 (in VDD_CORE)
WKUP_VTM_TMPSENS_*_5	On VDD_CORE / VDD_CPU boundary near C7x / MMA (in VDD_CORE)
WKUP_VTM_TMPSENS_*_6	Near LPDDR4 in VDD_CORE (DDR)
Others	Unused

6.2.4.2.4.2.3 VTM ECC Aggregator

Note

For more information about ECC Aggregator functionality, see *ECC Aggregator*.

6.2.4.2.4.2.4 VTM Programming Model

6.2.4.2.4.2.4.1 VTM Maximum Temperature Outrange Alert

THERM_MAXTEMP_OUTRANGE_ALERT is used at the device level in order to generate device warm reset. The alert is asserted when the device overheats and exceeds the maximum temperature limit specified for the device, namely 125°C.

The following is the sequence to assert the THERM_MAXTEMP_OUTRANGE_ALERT:

Copyright © 2026 Texas Instruments Incorporated

1. For the output to go active (‘1’), the VTM has to be configured to operate with at least one of its temperature sensors enabled, and VTM_CFG1_TMPSENS_CTRL_j[11] MAXT_OUTRG_EN = 1 for the corresponding enabled sensor.
2. In addition, VTM_CFG2_MISC_CTRL[0] ANYMAXT_OUTRG_ALERT_EN has to be set to ‘1’.
3. With the previous configuration set and at least one of the temperature sensors properly configured, and enabled, if the temperature of the die ever exceeds the programmed value in VTM_CFG2_MISC_CTRL2, the VTM output will be driven ‘1’ once the sensor detects the programmed maximum temperature.
4. At the device level the VTM output, THERM_MAXTEMP_OUTRANGE_ALERT, will drive the PLL controllers into warm reset state with the PLL controllers entering warm reset condition, at the same time that all the PLLs go into clock bypass mode.
5. By the actions described in No.4, the device will considerably reduce its power consumption, which over the passing of a few seconds will cause the device to reduce its temperature.
6. The VTM sensor continues to read the temperature and once the code corresponding to the programmed value in VTM_CFG2_MISC_CTRL2[25-16] MAXT_OUTRG_ALERT_THR0 is detected the VTM drives THERM_MAXTEMP_OUTRANGE_ALERT = 0.
7. After No.6 is fulfilled, the PLL controllers no longer have the THERM_MAXTEMP_OUTRANGE_ALERT driving the warm reset request and thus the PLL controllers bring the SoC out of reset and the boot sequence re-starts. At the same time the PLLs get out of bypass mode and start with their target programmed frequencies for the boot process.

Note

THERM_MAXTEMP_OUTRANGE_ALERT output of VTM is mapped to VTM_CFG2_MISC_CTRL[0] ANY_MAXT_OUTRG_ALERT_EN.

Notice that exceeding of the programmed value in VTM_CFG2_MISC_CTRL2[9-0] MAXT_OUTRG_ALERT_THR boundary doesn’t result in a PORz (cold reset) event, but instead a warm reset event. Otherwise if cold reset is applied to the MCU/WKUP domains of the device, the VTM will be fully reset and the output THERM_MAXTEMP_OUTRANGE_ALERT will be cleared to ‘0’ immediately.

6.2.4.2.4.2.4.2 Sensors Programming Sequences

Sensors Control Modifications Sequence:

1. Write changes to registers.
2. Wait for 900ns to 1us (long enough for sensor period of slowest 1.15 MHz sensor clock plus some extra).
3. New changes can be written to registers.

Reset Sensors Sequence:

1. Set the WKUP_VTM_TMPSENS_CTRL_j[6] CLRZ bit to enable the sensor (so that it has the ENA input high).
2. Wait for 900ns to 1us for the sensor clock to toggle and register the updated ENA pin.
3. Clear WKUP_VTM_TMPSENS_CTRL_j[6] CLRZ to disable and reset the sensor (as it requires an ENA transition from 1 to 0 to reset initially) .
4. Wait for 900ns to 1us for the sensor clock to toggle and register the updated ENA pin.
5. Now the sensor can be configured and enabled normally.

6.2.4.2.4.2.5 AVS-Class0

Adaptive Voltage Scaling (AVS) Class 0 is a procedure for lowering the voltage on certain device power rails. AVS Class 0 attempts to normalize the power consumption across all devices. The optimal voltage for each AVS supported rail of each device is determined after analysis in the factory, based on the strength of the device during manufacturing. This value is written in the device eFuse where it can be read through dedicated registers.

AVS can be enabled by system software after primary boot. Refer to *AVS Support* on how to enable AVS based on these registers.

6.3 Reset

This chapter describes the device reset signals and contains details on reset management.

6.3.1 Overview

Reset Introduction

A reset is designed to bring a device or subsystem into a known state. Resets occur after power up events, as well as through software and hardware reset requests. This section introduces the device reset capabilities and functionality.

Device Resets

The Device Power-on-Reset (POR) is controlled by the external pin MCU_PORz. This pin is driven by an external (off-chip) "Power-Good" Circuit or Power Management IC (PMIC). The MCU_PORz pin should be held active LOW (0) during the entire power-up phase. The device should be held in reset until all power supplies are stable with an additional delay for the High Frequency Oscillator (HFOSC0) clock to stabilize.

The SoC is divided into two separate functional Reset Domains: MCU Reset Domain and MAIN Reset Domain (each containing specific processing cores and peripherals).

- MCU Reset Domain: Managed by the MCU Domain, PLLCTRL and PSC, this includes ARM® Cortex®- R5F MCU Processor (R5FSS).
- MAIN Reset Domain: Managed by the MAIN Domain, PLLCTRL and PSC, this includes the high performance application Arm Cortex-A53 cores (A53SS), Device Management and Low Power Management (DM R5F), Security Controller (SMS0) .

Both MCU and Main domains have independent Warm Reset MCU_RESETz & MAIN_RESETz_REQ pins. All MCU domain resets act as controller resets to the whole device, whereas Main domain resets only reset Main domain (MCU domain is reset isolated from all Main domain resets). The following section outlines the various resets coming from pins and software MMR bits and their behavior.

Figure 6-12 illustrates the high-level reset domain partition.

6.3.1.1 MCU Domain Supported Resets

- Power-On-Resets
  - MCU_PORx device pin: This power-on-reset will reset the entire device including MCU and MAIN domains.
- Warm Resets
  - MCU_RESETz device pin
  - MCU domain software warm reset
  - MCU domain ESM error reset
  - SMS cold reset

  The warm resets listed above will reset the entire device including MCU and MAIN domains.
- Local Module Resets
  - MCU domain LPSC module local reset: This reset is generated by the MCU PSC to locally reset the R5F CPU core

6.3.1.2 MAIN Domain Supported Resets

- Power-On-Resets
  - MAIN domain software POR reset
  - MAIN domain hardware POR reset generated by MCU_PORz
- Warm Resets
  - RESETz_REQ device pin
  - MAIN domain ESM error reset
  - MAIN domain software warm reset
  - SMS cold reset
  - MCU domain warm reset will also generate a MAIN domain warm reset
- Local Module Resets
  - MAIN domain LPSC module local reset: This reset is generated by the MAIN PSC to locally reset the Processor cores (A53, SMS R5F, DM R5F, PRUSS)

The device can be configured via software such that a Main domain resets can be isolated from MCU domain. When the MCU domain is configured for reset isolation, MAIN domain resets will only reset the MAIN domain and the MCU domain will remain unaffected by all MAIN domain resets. All MCU domain resets will cause a reset to the entire device (including MAIN and MCU domains).

6.3.1.3 High-Level Reset Flow

6.3.3 Reset Status

Reset Status shows the Reset Status functionality. An output pin or software bit is used to represent the status of a specific individual reset.

Table 6-34. Reset Status

Reset Status Name	Reset Status Source	Reset Status Info	Signal Active Level	Reset Signal Details
MCU_CTRL_MMR_CFG0_RST_STAT Status Register	Register	4 bits in CTRLMMR on MCU warm reset status and assertion.	Status bits read active HIGH (1) when a particular reset is asserted.	
WKUP_CTRL_MMR_CFG0_RST_STAT Status Register	Register	4 bits in CTRLMMR on WKUP warm reset status and assertion.	Status bits read active HIGH (1) when a particular reset is asserted.	
PORz_OUTz	Output Pin	On/Off pin status of MAIN PORz reset	Active LOW (0)	MAIN_PORz_OUT Status Pin
RESETSTATz	Output Pin	On/Off pin status of MAIN warm reset	Active LOW (0)	MAIN_RESETSTATzStatus Pin
MCU_RESETSTATz	Output Pin	On/Off pin status of MCU PORz reset	Active LOW (0)	MCU_RESETSTATz Status Pin
MCU_ERRORn	Output Pin	On/Off pin status of MCU ESM_ERROR reset	Active LOW (0)	MCU_SAFETY_ERRORn Status Pin

Copyright © 2026 Texas Instruments Incorporated

6.3.3.1 Reset Source Status Registers

All warm reset sources which trigger a device/domain warm reset are captured in the MCU domain CTRLMMR reset status register **MCU_CTRL_MMR_CFG0_RST_SRC**. This register is only reset on MCU_PORz.

The MCU domain CTRLMMR **MCU_CTRL_MMR_CFG0_RST_SRC** register is shadowed in WKUP domain CTRLMMR **WKUP_CTRL_MMR_CFG0_RST_SRC** so that MAIN domain processors can read it without directly accessing the MCU domain CTRLMMR.

After recovery from warm reset, software can read the CTRLMMR reset source register **WKUP_CTRL_MMR_CFG0_RST_SRC** to identify the source of previous reset. After reading this reset source register, software must clear the register by writing to the MCU domain CTRLMMR, **MCU_CTRL_MMR_CFG0_RST_SRC**.

Reset status bits read active HIGH (1) when a particular reset is triggered.

The following reset sources, which cause MCU and MAIN domain resets, are captured in the MCU domain CTRLMMR reset source register:

- MCU_RESETz (Reset by Hardware Pin)
- SW_MCU_WARMRSTz (Reset by MCU domain CTRLMMR [1])
- SW_MAIN_PORz_MCUMMR (Reset by MCU domain CTRLMMR [1])
- SW_MAIN_PORz_MAINMMR (Reset by MAIN domain CTRLMMR [1])
- MAIN_RESET_REQz (Reset by Hardware Pin)
- SW_MAIN_WARMRSTz_MCUMMR (Reset by MCU domain CTRLMMR [1])
- SW_MAIN_WARMRSTz_MAINMMR (Reset by MAIN domain CTRLMMR [1])
- SMS_COLD_OUT_RST_n (Reset by SMS)
- SMS_WARM_OUT_RST_n (Reset by SMS)
- THERM_MAXTEMP_OUTRANGE_ALERT (Reset by VTM Max Temperature Alert)
- SYSR_ASSERTRESET_n (Reset by DEBUGSS)
- ESM_ERROR_RST_n (Reset by ESM Error)
- DM_WDT RST_n (Reset by WKUP WDT Timeout during Deepsleep mode)
- DM_MAIN_PORz (Reset by DS_MAIN_POR_PDOFF a WKUP domain CTRLMMR [1] during deepsleep)
  - MCU ESM Error will reset entire device
  - MAIN ESM Error will only reset MAIN domain when MCU domain is isolated. When MCU domain is not isolated, it will warm reset both MCU and MAIN domains.

Note

1. MAIN domain software WARMRSTz and PORz control registers are defined in both WKUP domain CTRLMMR and MCU domain CTRLMMR.

When the MCU domain is isolated from MAIN domain, MCU R5FSS processor can reset the MAINdomain, by programming the reset control registers defined in the MCU domain CTRLMMR. This way MCU R5FSS does not need to access MAIN domain CTRLMMR for MAIN domain reset action.

Whena MAIN domain processor (A53, SMS, R5F) needs to issue resets to MAIN domain on error detection they will use the WARMRESETz and PORz MMR bits defined in the WKUP domain CTRLMMR.

6.3.3.2 MCU_RESETSTATz Status Pin

The MCU_RESETSTATz pin indicates the internal reset status of the device (active LOW). When LOW, it indicates that the MCU and MAIN domains are in warm reset state. When HIGH, it indicates that the MCU is out of warm reset state. Refer to Section 6.3.3.4 for MAIN domain reset status.

Copyright © 2026 Texas Instruments Incorporated

6.3.3.3 MCU_ERRORn Status Pin

The MCU_ERRORn pin indicates the MCU domain ESM status. This Output is used to signal an external agent that it needs to (or may need to) intervene because of an error. The Error Pin Output is active Low or PWM, based on the ESM Error Pin Control register pwm_en field (Refer ESM IP) . This pwm_en field should only be modified when the ESM is disabled, based on the Global Enable register. Refer ESM chapter for details.

While in Power-On-Reset, the Error Pin is active (asserted low). SoC drives a Low via a weak internal pull-down. After Power-On-Reset condition is removed, ESM will drive the Error Pin. During a Warm Reset the state of the Error Pin is unchanged (i.e. the Error Pin logic is only reset by asserting MCU_PORz low).

When MCU_ERRORn output pin is configured to operate in level mode, a LOW indicates the MCU ESM module has registered an error. A HIGH indicates that there are no MCU ESM errors.

When MCU_ERRORn output pin is configured to operate in PWM mode, no error is indicated by continuous toggle according to programmable MMR widths for high and low periods. When an error occurs, the error pin stops toggling and remains constant until the error is cleared. An external device (such as a PMIC) that is detecting the PWM toggles can identify the error if the pin stops toggling. The periods should be programmed such that they fit within the expectation of the external device.

Note

This signal can be used by external safety devices to determine the device status and assert MCU_PORz if necessary.

6.3.3.4 RESETSTATz Status Pin

This pin indicates warm reset status (active LOW) of the MAIN domain.

When LOW, it indicates that the MAIN domain is in a warm reset state.

When HIGH, it indicates that the MAIN domain is out of reset.

The status of this signal will be captured in WKUP_CTRL_MMR1 registers.

6.3.3.5 PORz_OUT Status Pin

This pin indicates the POR status of the MAIN domain (active LOW).

When LOW, it indicates the MAIN domain is in the POR state.

When HIGH, it indicates the MAIN domain is out of the POR state.

Note

PORz_OUT may be used to enable and/or disable output buffers of attached devices that share pins associated with BOOTMODE inputs, such that appropriate boot configuration values are allowed to propagate into the device without contention.

Copyright © 2026 Texas Instruments Incorporated

6.3.4 Reset Controls

The reset control registers enable, disable, and adjust specific reset operations. This section explains how to control certain device resets.

6.3.4.1 Reset Control Registers

MCU Domain Reset Control Registers shows the CTRLMMR registers that are able to enable and disable reset abilities and options.

Table 6-35. MCU Domain Reset Control Registers

Control Name	Control Action	Control Register
MCU_ESM_ERROR_RST_ENz	Enable MCU ESM_ERRORz reset	**MCU_CTRL_MMR_CFG0_RST_CTRL**
SMS_COLD_RESET_ENz	Enable SMS cold reset of MCU domain	**MCU_CTRL_MMR_CFG0_RST_CTRL**

Table 6-36. MAIN Domain Reset Control Registers

Control Name	Control Action	Control Register
MAIN_ESM_ERROR_RST_ENz	Enable MAIN ESM_ERRORz Reset	**WKUP_CTRL_MMR_CFG0_RST_CTRL**
SMS_COLD_RESET_ENz	Enable SMS Cold Reset of MAIN Domain	**WKUP_CTRL_MMR_CFG0_RST_CTRL**

Note

For more information, see *Control Module (CTRLMMR)*.

6.3.4.2 Reset Isolation

Reset Isolation Introduction

It is possible to isolate certain SoC modules and subsystems and prevent them from undergoing an arbitrarily generated warm reset. This is known as Reset Isolation. This section describes the device reset isolation capabilities.

Simple Reset Isolation Sequence Diagram shows a simple description of the device reset isolation sequence.

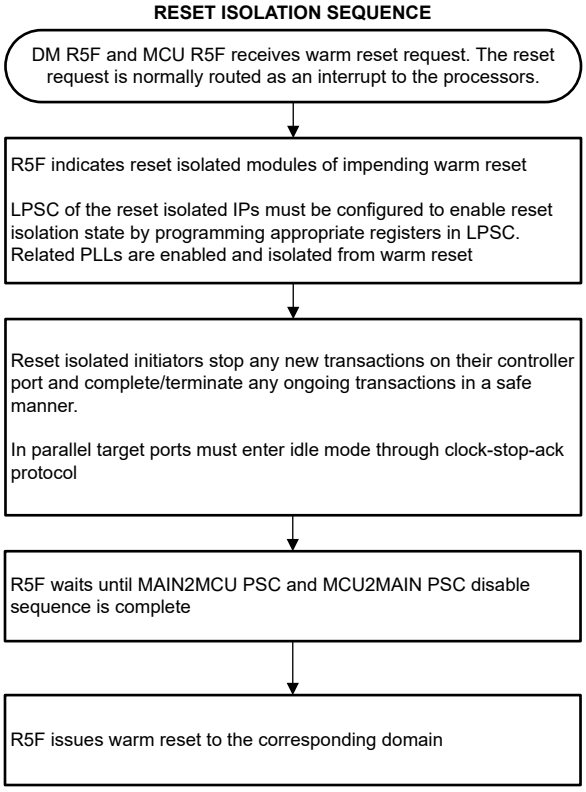

Figure 6-19. Simple Reset Isolation Sequence Diagram

MCU Reset Isolation Details

Detailed Reset Isolation Sequence Diagram shows a detailed description of the MCU reset isolation sequences.

6.3.5 Reset Details

Reset Details Introduction

The Reset Details section will break down the available device resets and explain operating details such as sequencing and reset logic diagrams. It also includes any additional information related to the device resets.

Copyright © 2026 Texas Instruments Incorporated

6.3.5.1 POR Resets

6.3.5.1.1 SW_MAIN_PORz Reset

Reset Overview

This reset is a software controlled MAIN domain POR reset defined in **WKUP_CTRL_MMR_CFG0_RST_CTRL** and **MCU_CTRL_MMR_CFG0_RST_CTRL**.

This software reset will generate a MAIN domain PORz.

R5FSS processor in MCU domain can trigger PORz to the MAIN domain by writing to the **MCU_CTRL_MMR_CFG0_RST_CTRL** register.

MAIN domain processors can reset the MAIN domain by writing to the **WKUP_CTRL_MMR_CFG0_RST_CTRL** register.

When the MCU domain is configured as a safety domain it must be isolated from SW_MAIN_PORz.

A reset isolation sequence for the MCU domain must be complete prior to reset propagation.

WKUP_CTRL_MMR_CFG0_RST_CTRL and **MCU_CTRL_MMR_CFG0_RST_CTRL** define a 4-bit field, SW_MAIN_POR[7:4], for generating a software-controlled POR for the MAIN domain (SW_MAIN_PORz).

When SW_MAIN_POR [7:4] field is set to “0110”, the MAIN domain is in POR reset state (SW_MAIN_PORz = LOW).

When SW_MAIN_POR [7:4] is set to any other value, the MAIN domain is out of POR reset state (SW_MAIN_PORz = HIGH).

This bit field is reset to “1111” (Inactive State) by default.

MCU Domain Effect

When MCU domain is configured as an independent domain, then the entire MCU domain is reset isolated. When MCU domain is not configured as independent domain then this SW_MAIN_PORz must not be used. Instead MCU_PORz pin functions should be used.

MCU IOs are not affected.

MAIN Domain Effect

All modules in MAIN domain are reset (including reset isolated modules).

IOs will enter safe state (as defined in the BALL STATE DURING RESET column of the Datasheet Pin Attributes table while this reset is active.

MAIN domain CTRLMMR boot configuration register is reset.

Device BOOTMODE pins will be re-latched after this reset is de-asserted.

Device will re-boot. During boot-up, R5FSS (secondary boot loader) will poll the CTRLMMR reset status and MCU ACTIVE MAGIC WORD registers and configure MCU domain/R5FSS processor accordingly.

Additional Details

PORz_OUT:

This pin indicates POR status output of the MAIN domain (active LOW).

When LOW, it indicates the MAIN domain is in POR state.

When HIGH, it indicates that the MAIN domain is out of POR state.

Copyright © 2026 Texas Instruments Incorporated

Note

PORz_OUT may be used to enable and/or disable output buffers of attached devices that share IOs associated with BOOTMODE inputs, such that appropriate boot configuration values are allowed to propagate into the device without contention

Note

The boot mode pins are latched internally on the rising edge of PORz_OUT and are reset isolated from all other device resets.

6.3.5.1.2 MCU_PORz Reset

Reset Overview

This is the POR reset signal (active LOW) for the entire device, controlled by the MCU_PORz HW Pin.

When LOW, it performs a POR reset on the entire device (MCU and MAIN domains) and puts IOs in a safe state (as defined in the BALL STATE DURING RESET column of the datasheet Pin Attributes table).

MCU Domain Effect

All modules in MCU domain are reset.

MCU IOs are in HHV state (Reset State).

When MCU_PORz is de-asserted, MCU IOs will enter the default state defined in the device Datasheet. MCU domain will be reconfigured by the device boot processor (secondary boot loader).

MAIN Domain Effect

All modules in the MAIN domain are reset.

MAIN domain IOs are in HHV state (as defined in the BALL STATE DURING RESET column of the datasheet Pin Attributes table).

When MCU_PORz is de-asserted, the MAIN domain IOs will enter default state as defined in the BALL STATE AFTER RESET column of the datasheet Pin Attributes table.

The device boot processor (secondary boot loader) will setup R5FSS as Safety or General-Purpose Processor.

6.3.5.2 Warm Resets

6.3.5.2.1 MAIN Domain Warm Reset Sequence Flow

MAIN Domain Warm Reset Sequence Flowchart explains the process for a typical MAIN domain warm reset.

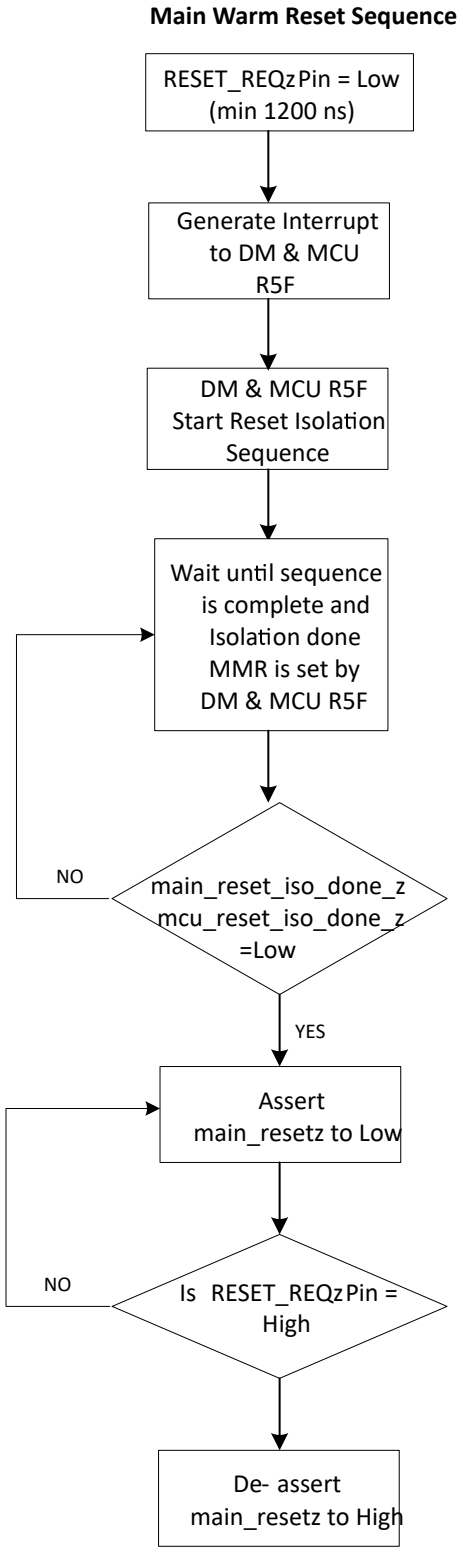

Figure 6-21. MAIN Domain Warm Reset Sequence Flowchart

Copyright © 2026 Texas Instruments Incorporated

6.3.5.2.2 MAIN_RESETz_REQ Reset

Reset Overview

This reset signal is the MAIN domain warm reset request (active LOW) controlled by the RESET_REQz HW pin.

When LOW is detected, reset hardware generates an interrupt to processors (A53SS/R5FSS) so they can complete the reset isolation sequence before reset is propagated.

MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to MAIN domain.

MCU IOs are not affected.

When MCU domain is not configured as independent, then this reset will also warm reset MCU domain.

MAIN Domain Effect

This is a MAIN domain warm reset request. First, the reset isolation sequence is applied and then the reset is propagated.

All modules in MAIN domain are reset except for warm reset isolated modules and MAIN domain CTRLMMR register bits which are reset only on MAIN_PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in the CTRLMMR reset source register **WKUP_CTRL_MMR_CFG0_RST_SRC**. After reset is de-asserted, device will boot-up. During device boot-up, DM R5F secondary boot loader will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU R5F processor accordingly.

Reset Sequence

The RESET_REQz reset sequence is described below.

RESET_REQz Sequence shows the timing between the RESET_REQz reset signal and the internal RESETz (MAIN domain warm reset) signal. Refer to the datasheet for timing and pulse width requirements.

Copyright © 2026 Texas Instruments Incorporated

MAIN WARM RESET (RESET_REQz Pin)

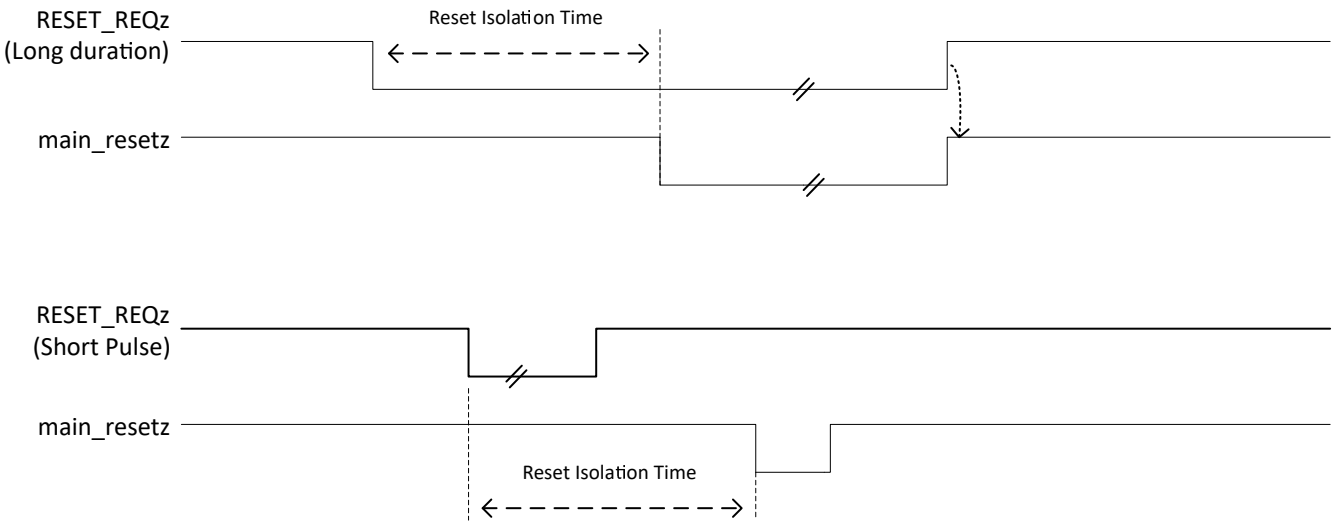

Figure 6-22. RESET_REQz Sequence

Additional Reset Details

RESETSTATz:

The RESETSTATz pin indicates the MAIN domain internal reset status (active LOW). This is a reflection of the reset status after the RESET_REQz reset signal (RESET_REQz HW Pin) is asserted.

When LOW, it indicates that the MAIN domain is in internal reset state.

When HIGH, it indicates that the MAIN domain is out of internal reset state.

RESETSTATz Timing shows the timing between the RESET_REQz reset signal and the RESETSTATz output. Refer to the datasheet for timing and pulse width requirements.

Copyright © 2026 Texas Instruments Incorporated

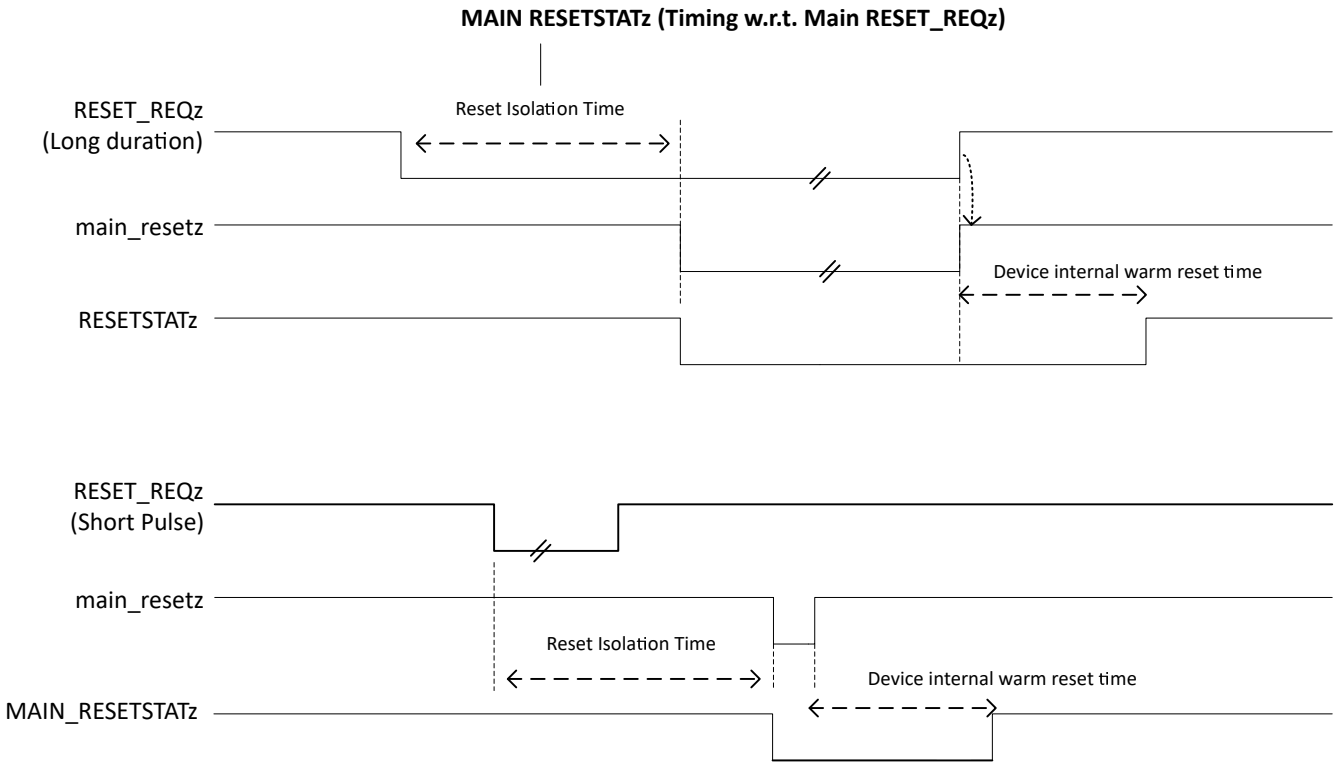

Figure 6-23. RESETSTATz Timing

Note

For more details see MAIN_RESETSTATz Status Pin.

Copyright © 2026 Texas Instruments Incorporated

6.3.5.2.3 SW_MAIN_WARMRSTz Reset

Reset Overview

This reset is software controlled MAIN domain warm reset defined in **WKUP_CTRL_MMR_CFG0_RST_CTRL** and **MCU_CTRL_MMR_CFG0_RST_CTRL**.

The R5FSS can issue a warm reset to the MAIN domain, by writing to the MCU domain CTRLMMR register.

The MAIN domain processors can issue a warm reset the WKUP domain, by writing to the MAIN domain CTRLMMR register.

Note

When R5FSS is configured as safety processor it must be reset isolated from this MAIN domain warm reset.

A reset isolation sequence for MCU domain has to be complete prior to this reset propagation.

WKUP domain CTRLMMR and MCU domain CTRLMMR registers define a 4-bit field, SW_MAIN_WARMRST[3:0] for generating a software controlled warm reset for the MAIN domain (SW_MAIN_WARMRSTz).

When SW_MAIN_WARMRST[3:0] field is set to “0110”, a MAIN domain warm reset is active (SW_MAIN_WARMRSTz = LOW).

When SW_MAIN_WARMRST[3:0] is set to any other value, the MAIN domain warm reset is inactive (SW_MAIN_WARMRSTz = HIGH).

This bit field is reset to “1111” (Inactive State) by default.

Note

This software reset is equivalent to RESET_REQz reset signal (RESET_REQz HW Pin) functionality.

MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

MAIN Domain Effect

This is a MAIN domain reset request. First, the reset isolation sequence is applied and then the reset is propagated.

All modules in MAIN domain are reset except for reset isolated modules and MAIN domain CTRLMMR register bits which are reset only on MAIN_PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in MAIN domain CTRLMMR reset status register **WKUP_CTRL_MMR_CFG0_RST_STAT**. After reset is de-asserted, device will boot-up. During device boot-up, R5FSS (secondary boot loader) will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/R5FSS processor accordingly.

Copyright © 2026 Texas Instruments Incorporated

6.3.5.2.4 MCU_RESETz Reset

Reset Overview

The MCU_RESETz signal is the warm reset input (active low) to the entire device, controlled by the MCU_RESETz HW Pin.

When active, it resets all modules in the MCU and MAIN domains.

MCU_RESETz will not reset selected **WKUP_CTRL_MMR_CFG0_RST_CTRL** and **MCU_CTRL_MMR_CFG0_RST_CTRL** register bits. These bits are only reset by PORz.

MCU Domain Effect

All modules in MCU domain are reset except for **MCU_CTRL_MMR_CFG0_RST_CTRL** bits which are reset only on MCU_PORz.

IOs are not affected.

R5FSS is reset.

When MCU_RESETz is de-asserted, the MCU domain needs to be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only by PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When MCU_RESETz is de-asserted, the device goes through full boot. The reason for this reset is captured in the CTRLMMR reset source register **MCU_CTRL_MMR_CFG0_RST_SRC**.

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/R5FSS processor accordingly.

Additional Details

MCU_RESETSTATz:

This pin indicates internal MCU_RESETz reset status (active LOW).

When LOW, it indicates that the device, both MCU and MAIN domains, are in internal reset state.

When HIGH, it indicates that the device MAIN domains, are is out of internal reset state.

Note

In order for the MAIN domain to come out of reset, RESETz_REQ (RESET_REQz HW Pin) must also be de-asserted.

Note

For more details see MCU_RESETSTATz Status Pin.

Copyright © 2026 Texas Instruments Incorporated

6.3.5.2.5 SW_MCU_WARMRSTz Reset

Reset Overview

This is a software MCU domain warm reset defined in MCU domain CTRLMMR.

MCU CTRLMMR defines a 4-bit field, SW_MCU_WARMRST[11:8] for generating a software warm reset in the MCU domain (SW_MCU_WARMRSTz).

When SW_MCU_WARMRST[11:8] field is set to “0110”, MCU warm reset is active (SW_MCU_WARMRSTz = LOW).

When SW_MCU_WARMRST[11:8] is set to any other value, MCU warm reset is inactive (SW_MCU_WARMRSTz = HIGH).

This bit field is reset to “1111” (Inactive State) by default.

Note

This software reset is equivalent to MCU_RESETz warm reset signal (MCU_RESETz HW Pin) functionality.

MCU Domain Effect

All modules in the MCU domain are reset except for MCU domain CTRLMMR bits which are reset only on MCU_PORz.

IOs are not affected.

R5FSS processor is reset.

When MCU_RESETz is de-asserted, the MCU domain needs to be reconfigured by the R5FSS (secondary boot loader) in the MAIN domain.

MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When MCU_RESETz is de-asserted, the device goes through full boot. The reason for this reset is captured in CTRLMMR reset source register**WKUP_CTRL_MMR_CFG0_RST_SRC**.

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD and reconfigure the MCU domain/R5FSS processor accordingly.

Copyright © 2026 Texas Instruments Incorporated

6.3.5.3 SMS Resets

6.3.5.3.1 SMS_WARM_OUT_RST_n Reset (MAIN Domain)

Reset Overview

The SMS will issue this reset upon a security error.

When this reset is enabled in MAIN domain, it causes a MAIN domain warm reset.

This is a synchronous reset type (needs to complete reset isolation sequence).

Note

This reset behavior is same as the RESETz_REQ reset signal (RESET_REQz HW Pin).

MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

MAIN Domain Effect

This is a MAIN domain warm reset request. First, the reset isolation sequence is applied and then the reset is propagated.

All modules in MAIN domain are reset except for CTRLMMR register bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in CTRLMMR reset source status register **WKUP_CTRL_MMR_CFG0_RST_SRC**. After reset is de-asserted, device will boot-up. During device boot-up, R5FSS (secondary boot loader) will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/R5FSS processor accordingly.

6.3.5.3.2 SMS_COLD_OUT_RST_n Reset (MAIN Domain)

Reset Overview

This reset is a MAIN domain warm reset that is executed from the SMS. This is an asynchronous reset type (takes effect immediately). This SMS reset of the Main domain is enabled only when the SMS_COLD_RESET_EN_z bit in WKUP domain CTRLMMR is '0'.

Note

This reset behavior is same as the RESETz_REQ reset signal (RESET_REQz HW Pin) with the exception that it takes effect immediately without need for any reset isolation sequence.

MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

Copyright © 2026 Texas Instruments Incorporated

MAIN Domain Effect

This is a MAIN domain asynchronous warm reset. Propagates immediately wihout any reset isolation sequence.

All modules in MAIN domain are reset except CTRLMMR register bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

Reason for this reset is captured in CTRLMMR reset status register. After reset is de-asserted, device will boot-up. During device boot-up, R5FSS (secondary boot loader) will read the reset status and MCU ACTIVE MAGIC WORD registers and reconfigure the MCU domain/R5FSS processor accordingly.

Copyright © 2026 Texas Instruments Incorporated

6.3.5.3.3 SMS_COLD_OUT_RST_n Reset (MCU Domain)

Reset Overview

The device SMS will issue this reset upon a security error.

When this reset is enabled in MCU domain, it causes a whole device warm reset.

This SMS reset of the MCU domain is enabled only when the SMS_COLD_RESET_ENz bit in MCU domain CTRLMMR is '0'.

When the R5FSS is configured as a safety processor, it can block this reset from resetting the MCU domain.

This is an asynchronous reset type (takes effect immediately)

Note

This reset behavior is same as MCU_RESETz reset signal (MCU_RESETz HW Pin).

MCU Domain Effect

All modules in MCU domain are reset except for CTRLMMR bits which are reset only on MCU_PORz.

IOs are not affected.

R5FSS is reset.

When MCU_RESETz is de-asserted, the MCU domain will be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When MCU_RESETz is de-asserted, the device goes through full boot. The reason for this reset is captured in the CTRLMMR reset source register **WKUP_CTRL_MMR_CFG0_RST_SRC**.

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD and reconfigure the MCU domain/R5FSS processor accordingly.

Copyright © 2026 Texas Instruments Incorporated

6.3.5.4 VTM Thermal Alert Reset

Reset Overview

The VTM has a hardware alert signal that indicates a fault when any of the sensors listed in *Voltage and Thermal Manager Locations* detect that the device is nearing the maximum temperature allowed.

This alert can be used to reset the device or part of the device to reduce the temperature. This alert is not a standard interrupt and so it does not include the usual set, clear and enable features. It does include an overall enable MMR bit, VTM_CFG2_MISC_CTRL, along with enables per sensor from VTM_CFG1 Registers.

The VTM module outputs an alert signal (THERM_MAXTEMP_OUTRANGE_ALERT), when the device temperature goes beyond a maximum threshold.

This reset signal creates a MCU domain warm reset.

VTM alert will be active as long as the error condition (Device Temperature > Maximum Temperature Threshold) is still TRUE.

When the error goes away, VTM alert will be de-asserted and device will come out of warm reset.

Note

This signal, when asserted HIGH, will cause a device warm reset similar to MCU_RESETz.

MCU Domain Effect

All modules in MCU domain are reset except for MCU domain CTRLMMR bits which are reset only on MCU_PORz.

IOs are not affected.

This reset is active as long as the VTM alert is active.

When THERM_MAXTEMP_OUTRANGE_ALERT is de-asserted, the MCU domain needs to be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on MAIN_PORz.

IOs are not affected.

All processor cores are reset (A53SS and R5FSS).

When THERM_MAXTEMP_OUTRANGE_ALERT is de-asserted, the device goes through full initialization procedure. The reason for this reset is captured in the CTRLMMR reset source register **WKUP_CTRL_MMR_CFG0_RST_SRC**.

Additional Reset Details

VTM alert use-case example:

VTM sends out a warning signal before generating the Max Temp Alert.

There are 2 different threshold settings for max temperature limits.

The first one has a lower threshold which will generate an interrupt to the processor for taking action to reduce frequency, turn-off power domains, etc. This should eventually lower the temperature and avoid the Max Temp Alert.

Copyright © 2026 Texas Instruments Incorporated

If the interrupt does not fix the rising temperature, then VTM will issue a Max Temp Alert. This will cause a device warm reset. The VTM Max Temp Alert will be active as long as die temperature is above the programmed threshold.

Device warm reset will default certain power domains to off mode (default at power-up). This should eventually lower the die temperature further.

Software can read the reset status register to poll on the cause of the warm reset. If it is from VTM, then it can wait for additional time before turning on the power domains.

Copyright © 2026 Texas Instruments Incorporated

6.3.5.5 MAIN ESM_ERRORz Reset

Reset Overview

This reset is issued when a MAIN domain processor (A53SS, SMS, or R5FSS) detects a catastrophic software error or a MAIN domain WDT timeout event occurs.

Errors in the MAIN domain cause the MAIN ESM module to trigger ESM_ERRORz.

This is routed as internal MAIN domain warm reset when enabled by the WKUP domain CTRLMMR reset control bit (MAIN_ESM_ERROR_RST_ENz).

This is an asynchronous reset type (takes effect immediately).

Reset MCU Domain Effect

When MCU domain is configured to operate independently, MCU domain reset isolation sequence is completed before propagating the RESETz to main domain.

MCU IOs are not affected.

When MCU domain is not configured as independent then, this reset will also warm reset MCU domain.

Reset MAIN Domain Effect

All modules in MAIN domain are reset except for MAIN domain CTRLMMR bits which are reset only on PORz.

IOs are not affected.

The device will re-boot. During boot-up, the R5FSS (secondary boot loader) will poll the CTRLMMR reset registers and reconfigure the MCU domain/R5FSS processor accordingly.

Note

If the device boot fails, and the MCU_ERRORn level is still LOW, then an external safety device should issue the MCU_PORz Reset to allow the device to recover from this error.

Copyright © 2026 Texas Instruments Incorporated

6.3.5.6 MCU ESM_ERRORz Reset

Reset Overview

This reset is issued when the R5FSS detects a catastrophic safety error or a MCU WDT timeout occurs.

Errors in the MCU domain cause the MCU ESM module to trigger error output.

This is routed as a device warm reset when enabled by the MCU domain WKUP_CTRL_MMR1 bit (MCU_ESM_ERROR_RST_ENz).

This is an asynchronous reset type (takes effect immediately).

MCU Domain Effect

All modules in MCU domain are reset except for MCU domain WKUP_CTRL_MMR1 bits which are reset only on PORz.

IOs are not affected.

Error is reported on MCU_ERRORn pin.

When SAFETY_ERROR_RST_n is de-asserted, the MCU domain needs to be reconfigured by the R5FSS (secondary boot loader) in the MAIN domain.

External hardware (PMIC or secondary MCU safety channel) must issue MCU_PORz to recover from this error.

MAIN Domain Effect

All modules in MAIN domain are reset except for reset isolated modules and MAIN domain WKUP_CTRL_MMR0 bits which are reset only on PORz.

IOs are not affected.

Device will re-boot. During boot-up, the R5FSS (secondary boot loader) will poll the CTRLMMR reset source register and configure the MCU domain/R5FSS processor accordingly.

If the device boot fails, and MCU_ERRORn level is still LOW, then an external safety device should issue the MCU_PORz reset to allow the device to recover from the error.

6.3.5.7 DM_WDT_RST_n Reset

Reset Overview

During Deeplseep resume sequence if the Device Manager is unable to respond due to a software bug, the WKUP domain WDT timer will issue this reset signal.

When this reset is enabled in MCU domain, it causes a whole device warm reset.

This WKUP WDT reset is enabled only when the DM_WDT_RST_EN_z bit in MCU domain CTRLMMR is '0'.

When the R5FSS is configured as a safety processor, it can block this reset from resetting the MCU domain. This is an asynchronous reset type (takes effect immediately)

Note

This reset behavior is same as MCU_RESETz reset signal (MCU_RESETz HW Pin).

MCU Domain Effect

All modules in MCU domain are reset except for MCU domain CTRLMMR bits which are reset only on MCU_PORz.

IOs are not affected. R5FSS is reset.

Copyright © 2026 Texas Instruments Incorporated

When this reset is de-asserted, the MCU domain will be reconfigured by R5FSS (secondary boot loader) in the MAIN domain.

MAIN Domain Effect

All modules in the MAIN domain are reset except for CTRLMMR bits which are reset only on PORz.

IOs are not affected.

All processor cores are reset (A53SS, SMS, and R5FSS).

When this reset is de-asserted, the device goes through full boot. The reason for this reset is captured inthe CTRLMMR reset source register.

During device boot-up, the R5FSS (secondary boot loader) will read the CTRLMMR reset status and MCU ACTIVE MAGIC WORD and reconfigure the MCU domain/R5FSS processor accordingly.

6.3.5.8 HHV

IOs support HHV mode during power up. HHV is active when PORz signal is driven LOW.

HHV allows IO cells to be tri-stated and is an IO feature. All IO cells have HHV which is asserted (driven) by HHV generated during PORz assertion. There are default pull values during this HHV/PORz assertion specified in the device Datasheet for each pin. All HHV logic controlling the buffer output enable and associated default internal pull for each IO will be applied.

HHV Timing Diagram demonstrates the timing sequence for the device HHV signals.

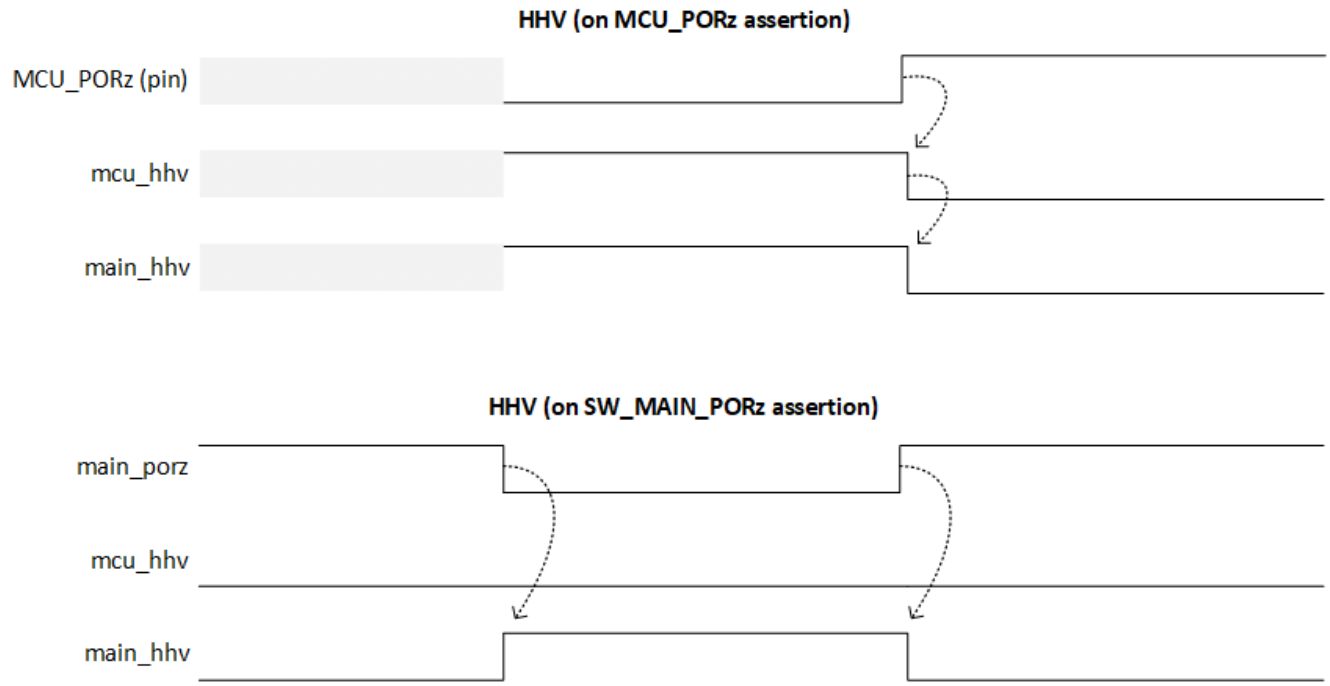

Figure 6-24. HHV Timing Diagram

6.3.5.9 BOOTMODE Pin Latching

This device requires several Boot Mode controls to enable device boot. The BOOTMODE inputs are not implemented on dedicated pins. They are multiplexed with other signal functions, where pins associated with the BOOTMODE inputs are defined in the Pin Attributes table. The logic state of the BOOTMODE inputs are latched on the rising edge of PORz_OUT. Valid logic states must be maintain as long as PORz_OUT is held low. The latched values are reflected in WKUP CTRL MMRs for read/write access.

6.4 Clocking

This chapter describes the clock architecture of the device.

6.4.1 Overview

To satisfy the various subsystems requirements, the device features multiple clock sources and clock generators:

- External Crystal Driver
- Internal Oscillator
- Phase-Locked Loop circuits (PLLs)
- Dividers

Figure 6-28 shows the device top-level clock diagram. The clocking is divided into two clocking domains - MCU and MAIN.

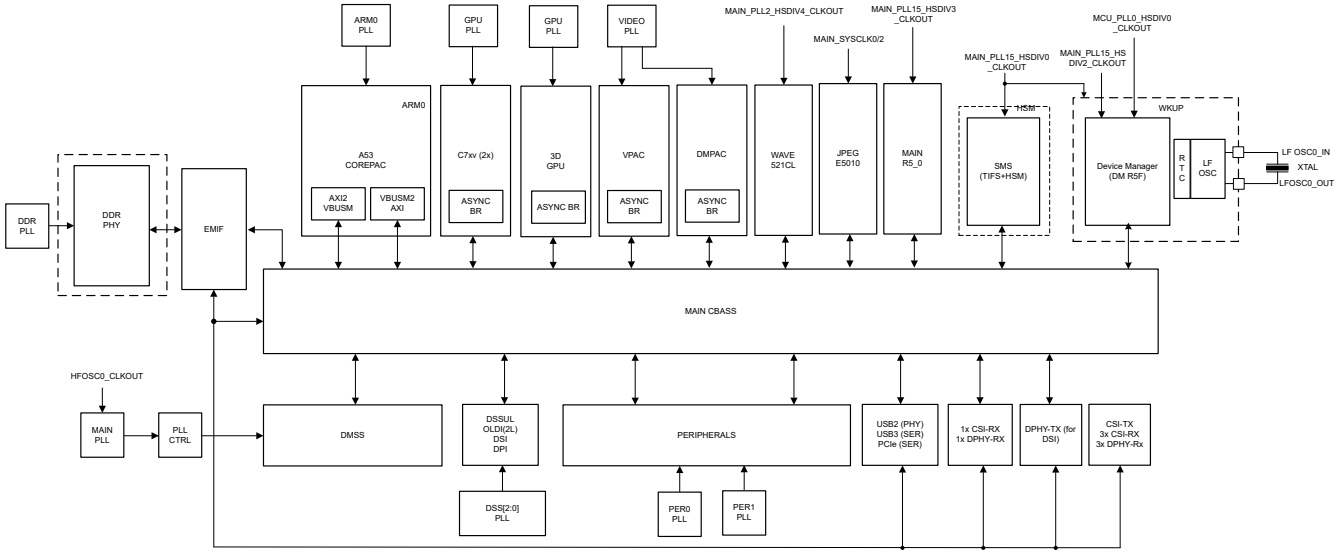

Figure 6-28. Top-Level Clock Diagram

Copyright © 2026 Texas Instruments Incorporated

6.4.2 Clock Inputs

6.4.2.1 Overview

Various external clock inputs are needed to drive the device. Summary of these input clock signals is as follows:

- High frequency oscillators
  - MCU_OSC0_XO/MCU_OSC0_XI — external main crystal interface pins of the internal oscillator which sources a reference clock. Provides reference clock to PLLs within MCU and MAIN domain.
- Low frequency oscillators
  - LSOSC0_IN/LFOSC0_OUT - external 32.768KHz crystal interface pins of the internal oscillator which sources a reference clock. Provides reference clock to RTC and Timers within MCU and MAIN domain.
- General purpose clock inputs
  - MCU_EXT_REFCLK0 — optional external system clock input (MCU domain).
  - EXT_REFCLK1— optional external system clock input (MAIN domain).
- External CPTS reference clock inputs
  - CP_GEMAC_CPTS0_RFT_CLK — CPTS reference clock input for CPSW and Timers in MAIN.
- External audio reference clock inputs/outputs
  - AUDIO_EXT_REFCLK[1:0] — optional McASP high-frequency input clocks when configured to operate as an input.

Note

Other clock inputs that are routed directly to the subsystems are described in the respective subsystem chapters.

Copyright © 2026 Texas Instruments Incorporated

6.4.3 Clock Outputs

The device provides several system clock outputs. Summary of these output clock signals is as follows:

- MCU_SYSCLKOUT0
- MCU_OBSCLK0
- SYSCLKOUT0
- OBSCLK0
- WKUP_CLKOUT0
- CLKOUT0
- AUDIO_EXT_REFCLK[1:0]
- AUDIO_EXT_REFCLK[2:0]

Other clock outputs, that are routed directly from subsystems to device pins, are described in the respective module chapter.

Observation clock pins - MCU_OBSCLK0 and OBSCLK0 serve the following purposes:

- During testing, PLLs on the device are configured to output all operating frequencies desired by each module to characterize PLL performance.
- System debug: during debug, clocks from various PLLs can be inspected for possible clues. Example clock glitches, lock loss etc.

Note

Maximum frequency supported on both MCU_OBSCLK0 and OBSCLK0 pins is 200 MHz. Hence the divider at the output of each OBSCLK mux must be programmed to meet this limitation.

Unlike the OBSCLK pins which can select several different clocks for output, system clock pins (MCU_SYSCLKOUT0 and SYSCLKOUT0) are hardwired to dedicated clock resources (see Section 6.4.3.2)

6.4.3.1 Observation Clock Pins

6.4.3.1.1 MCU_OBSCLK0 Pin

MCU_OBSCLK0 output is controlled by MCU_CTRL_MMR_CFG0_MCU_OBSCLK_CTRL register in the MCU_CTRL_MMR0 module; for more information about control registers, refer to *Control Module (CTRL_MMR)*. Two muxes are connected in series - MCU_OBSCLK0_MUX0 and MCU_OBSCLK0_MUX1, see Figure 6-29.

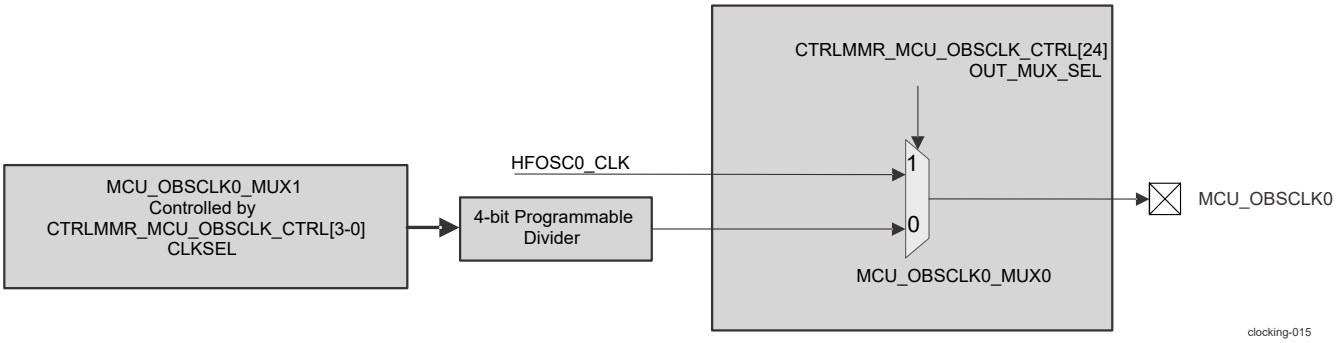

Figure 6-29. MCU_OBSCLK Muxes Diagram

How to select the output of MCU_OBSCLK0_MUX1 is described in Table 6-37.

Table 6-37. MCU_OBSCLK0_MUX1 Output Clock Selection

MCU_CTRL_MMR_CFG0_MCU_OBSCLK_CTRL[2] [3-0] CLK_SEL	MCU_OBSCLK0_MUX1 Output Clock Selection[1]

(1) Software-controlled 4-bit divider is used to obtain the divided versions of the clocks passed to MCU_OBSCLK1 mux
(2) For more information about control registers, refer to *Control Module (CTRL_MMR)*.
(3) GND - ground

The value of the software-controlled 4-bit divider is determined by the MCU_CTRL_MMR_CFG0_MCU_OBSCLK_CTRL[11-8] CLK _DIV field; for more information about control registers, see *Control Module (CTRL_MMR)*.

Note

MCU_OBSCLK1_MUX0 is provided as a low jitter output for HFOSC0_CLK. In this configuration, MCU_CTRL_MMR_CFG0_MCU_OBSCLK_CTRL[3-0] should be configured as 0x1 (1, selecting a logical low signal) and MCU_CTRL_MMR_CFG0_MCU_OBSCLK_CTRL[24] should be configured as 0x1.

6.4.3.1.2 OBSCLK0 Pin

The OBSCLK0 output pin is controlled by MAIN_CTRL_MMR_CFG0_OBSCLK0_CTRL register in the CTRL_MMR0 module; for more information about control registers, refer to *Control Module (CTRL_MMR)*. Figure 6-30 shows a block diagram of internal OBSCLK0 mux connections.

(1) Software-controlled 8-bit divider is used to obtain the divided versions of the clocks passed to output pins
(2) For more information about control registers, refer to *Control Module (CTRL_MMR)*.
(3) GND - ground

The value of the software-controlled 8-bit divider is determined by register MAIN_CTRL_MMR_CFG0_OBSCLK0_CTRL[15-8] CLK_DIV; for more information about control registers, refer to *Control Module (CTRL_MMR)*.

6.4.3.2 System Clock Pins

6.4.3.2.1 MCU_SYSCLKOUT0

MCU_SYSCLK0 is divided by 4 and then send out of the device as a LVCMOS clock signal (MCU_SYSCLKOUT0). This signal can be used to test if the specific device clock is functioning or not.

Note

MCU_SYSCLKOUT0 cannot be used as a clock source for external devices on the board.

6.4.3.2.2 SYSCLKOUT0

SYSCLK0 is divided by 4 and then send out of the device as a LVCMOS clock signal (SYSCLKOUT0). This signal can be used to test if the specific device clock is functioning or not.

Note

SYSCLKOUT0 cannot be used as a clock source for external devices on the board.

6.4.3.2.3 WKUP_CLKOUT0

The WKUP_CLKOUT0 output pin is controlled by the WKUP_CTRL_MMR_CFG0_CLKOUT_CTRL register in the WKUP_CTRL_MMR0 module; for more information about control registers, refer Control Module (CTRL_MMR). Figure 6-31 shows a block diagram of internal WKUP_CLKOUT0 mux connections.

0x6	CLK_12M_RC
0x7	HFOSC0_CLKOUT

(1) Software-controlled 8-bit divider is used to obtain the divided versions of the clocks passed to output pins.
(2) For more information about control registers, refer Control Module (CTRL_MMR).

6.4.4 Device Oscillators

The device has the possibility to source clocks of an external high-frequency oscillator - HFOSC0 and external 32.768KHz oscillator - LFOSC0. The device has also one internal RC oscillator - CLK_12M_RC.

6.4.4.1 Device Oscillators Integration

6.4.4.1.1 High-Frequency Oscillator with External Crystal

By default, HFOSC0 is enabled after PORz. It supports a bypass mode. In this mode, an external clock can be driven on the XI Pin.

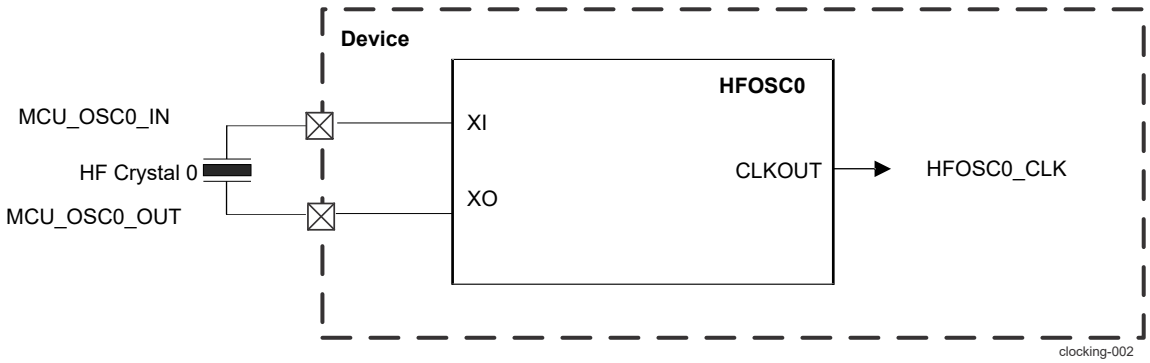

Figure 6-32. HFOSC0 Integration Diagram

6.4.4.1.2 Low-Frequency Oscillator with External Crystal

By default, LFOSC0 is disabled after PORz. It supports a bypass mode. In this mode, an external clock can be driven on the XI Pin.

Copyright © 2026 Texas Instruments Incorporated

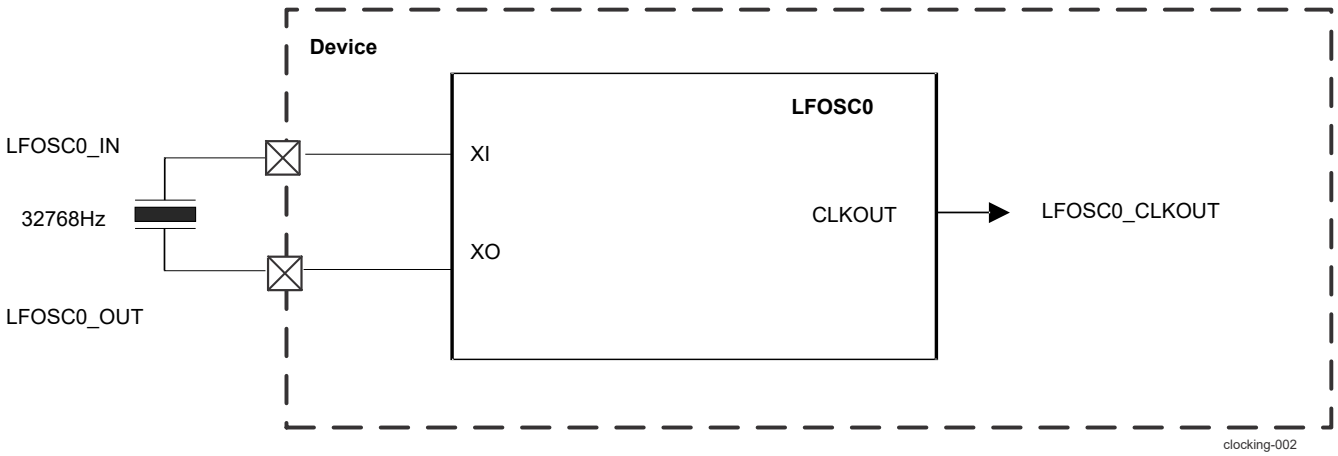

Figure 6-33. LFOSC0 Integration Diagram

6.4.4.1.3 Internal RC Oscillator

CLK_12M_RC in always oscillate mode.

The 12.5-MHz RC clock output (CLK_12M_RC) is used by the on-chip Reset Glue logic, Power Reset Generator (PRG) circuits, HFOSC0 Loss Circuits, Dual Clock Comparator (DCC) and Timer Modules.

Note

An output clock of CLK_12M_RC is further divided down to generate a 32-kHz clock (CLK_32K_RC). This clock is used by SMS and Timer Modules.

The actual value of the derived CLK_32K_RC will vary with PVT variations.

6.4.4.2 Oscillator Clock Loss Detection

The device supports HFOSC0 clock loss circuitry to detect when HFOSC0_CLK stops toggling. Dedicated hardware logic monitors HFOSC0 clock using CLK_12M_RC clock. When HFOSC0_CLK stops toggling for 9 CLK_12M_RC clock periods, a HFOSC0 clock stop loss condition is detected. If CTRLMMR_MCU_PLL_CLKSEL[8] CLKLOSS_SWTCH_EN is set , the reference clock is switched from HFOSC0_CLKOUT to CLK_12M_RC to allow the device to operate with a slower clock. The HFOSC0_CLK clock loss condition is reported as an error to MCU_ESM0 regardless of the value of MCU_CTRL_MMR_CFG0_MCU_PLL_CLKSEL[8] CLKLOSS_SWTCH_EN. Integration diagram of HFOSC0 clock loss detection is presented in Figure 6-34.

Copyright © 2026 Texas Instruments Incorporated

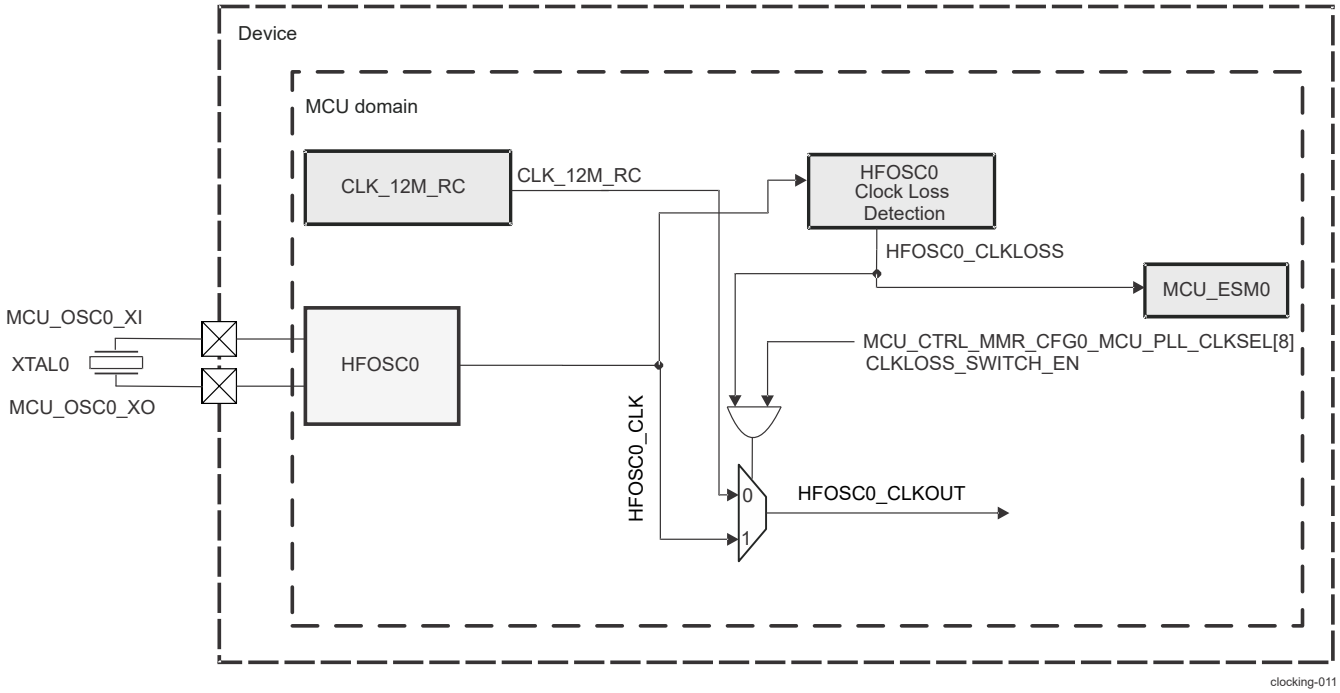

Figure 6-34. HFOSC0 Clock Loss Detection Integration Diagram

MCU_ESM0 can optionally generate an interrupt to MCU_ R5FSS and DM_R5FSS0 so they can save some critical contents such as error logging to scratch pad memory or external flash. ESM must also be configured to report this error on the MCU_ERRORn pin.

HFOSC0 clock loss is a catastrophic failure since this clock is the most critical system clock. During the clock loss condition an external system intervention is required.

The clock loss mux is not a glitch free mux. The mux control is synchronized to the CLK_12M_RC clock. Since HFOSC0_CLK has stopped switching the mux should transition to RC Clock without producing glitches.

During clock-loss condition, the device reports the error to the external device through MCU_ERRORn pin - the pin is driven Low. The recovery mechanism is up to the external system (such as a PMIC to take action). For example, it can try a full system power cycle to see if the system recovers. If the system does not recover then, it has to take some other action such as to check system clocks, external crystal or supply rails.

Device PLLs will lose lock when clock loss is detected. During this time 12.5-MHz RC clock is output through the bypass muxes. The PLL will relock to a new frequency based on 12.5 MHz RC clock.

In an event of clock glitch which may potentially hang the device, then the SMS watchdog timer will expire and will generate an internal reset for the whole device.

6.4.5 PLLs

Phase-Locked Loop circuits (PLLs) in the device are clock generator PLLs, which multiply the lower-frequency reference clock up to the operating frequency of the respective subsystem(s).

WARNING

PLL register descriptions are provided for debug purposes only. These registers should not be manipulated directly from software. PLL programming and configuration should only be performed using the appropriate APIs provided by TISCI services in TI's Processor Software Development Kits (SDKs). TISCI: Power Management (PM)

6.4.5.1 MCU Domain PLL Overview

MCU_PLL0 (MCU PLL) with MCU_PLLCTRL0 are present in the device in MCU domain. An overview is shown on Figure 6-35. For more specific information about PLLs see Section 6.4.5.5, *PLLs Device-Specific Information*.

Copyright © 2026 Texas Instruments Incorporated

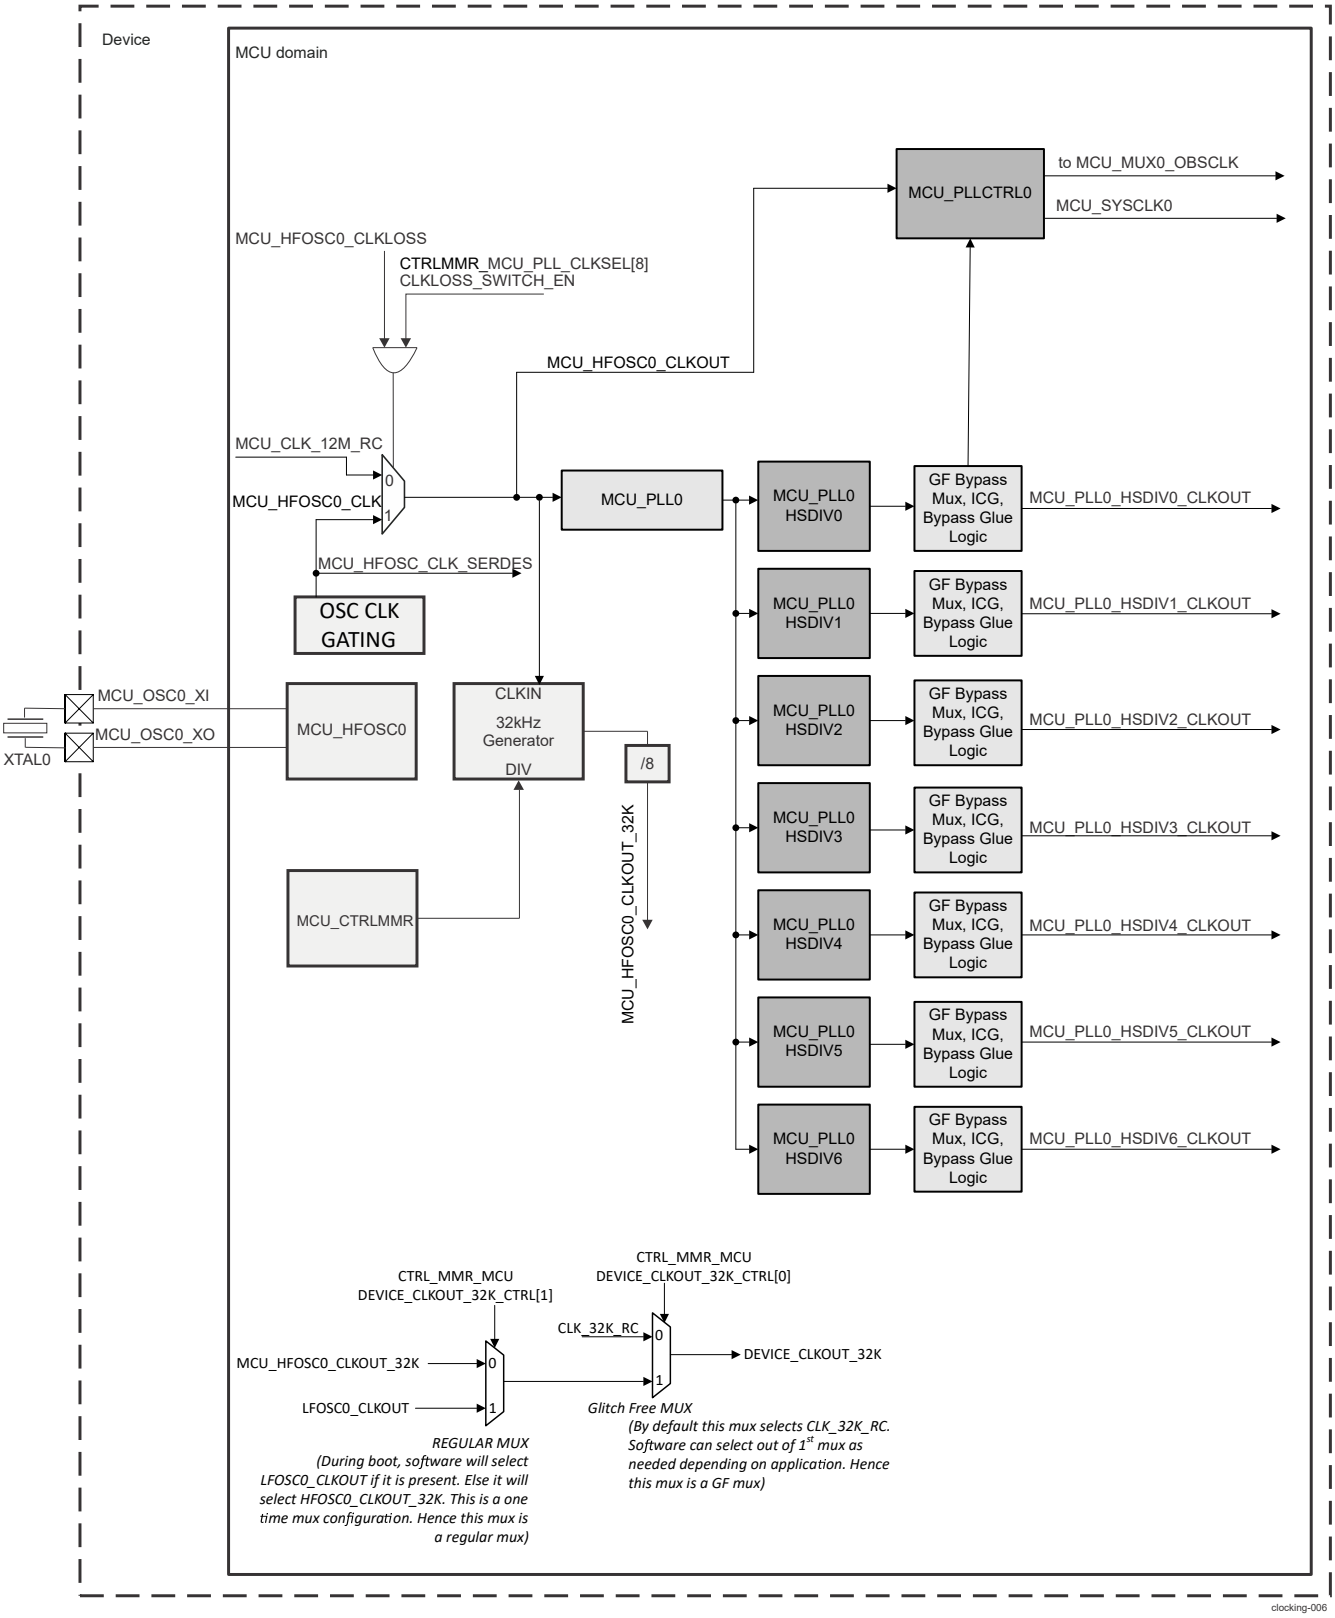

Figure 6-35. MCU Domain PLLs Integration

6.4.5.2 MAIN Domain PLLs Overview

The following are the PLLs in the device in MAIN domain:

- PLL0 (MAIN PLL) with PLLCTRL0
- PLL1 (PER0 PLL)
- PLL2 (PER1 PLL)
- PLL5 (VIDEO PLL)
- PLL6 (GPU PLL)
- PLL7 (C7x PLL)
- PLL8 (ARM0 PLL)
- PLL12 (DDR PLL)
- PLL15 (SMS PLL)
- PLL16 (DSS0 PLL)
- PLL17 (DSS1 PLL)
- PLL18 (DSS2 PLL)

Overview of the device PLLs with their reference clock options in MAIN domain is shown on Figure 6-36. For more specific information about PLLs see Section 6.4.5.5, *PLLs Device-Specific Information*.

Note

The external muxes of choosing the reference clocks are glitch-free muxes.

6.4.5.3 PLL Reference Clocks

6.4.5.3.1 PLLs in MCU Domain

The reference clock MCU_PLL0_REF_CLK for the PLL in MCU domain is chosen between the internal high-frequency (HF) oscillator with external crystal (HFOSC0) and 12.5-MHz free-running RC oscillator. The selection is made through MCU_CTRL_MMR_CFG0_MCU_PLL_CLKSEL[8] CLKLOSS_SWTCH_EN, see Table 6-40.

Table 6-40. PLL MCU Domain Reference Clock Selection - HFOSC0_CLKOUT Selection

MCU_CTRL_MMR_CFG0_MCU_PLL_CLKSEL(1)[8] CLKLOSS_SWTCH_EN	MCU_PLL0_REF_CLK
0 (default)	HFOSC0_CLK
1	CLK_12M_RC if clock loss is detected or HFOSC0_CLK if clock loss is not detected

(1) For more information about control registers, see *Control Module (CTRL_MMR)*.

6.4.5.3.2 PLLs in MAIN Domain

Each PLL in MAIN domain has a dedicated register (**MAIN_CTRL_MMR_CFG0_MAIN_PLLn_CLKSEL**, n = 0 to 2, 8, 12,15, 16, 17) in CTRL_MMR0 that contains associated control bits.

6.4.5.4 Generic PLL Overview

To generate high-frequency clocks, the device supports multiple on-chip PLLs controlled directly by the Top-level Clocking. Their type is Fractional PLL with Calibration (PLLTS16FFCLAFRACF2).

Note

This chapter discusses only the PLLs that are directly controlled by the Top-level Clocking. The other PLLs embedded in and managed by other subsystems are described in their respective subsystems.

6.4.5.4.1 PLLs Output Clocks Parameters

Figure 6-37 shows the functional architecture of a generic PLL for PLLTS16FFCLAFRACF2 type.

Copyright © 2026 Texas Instruments Incorporated

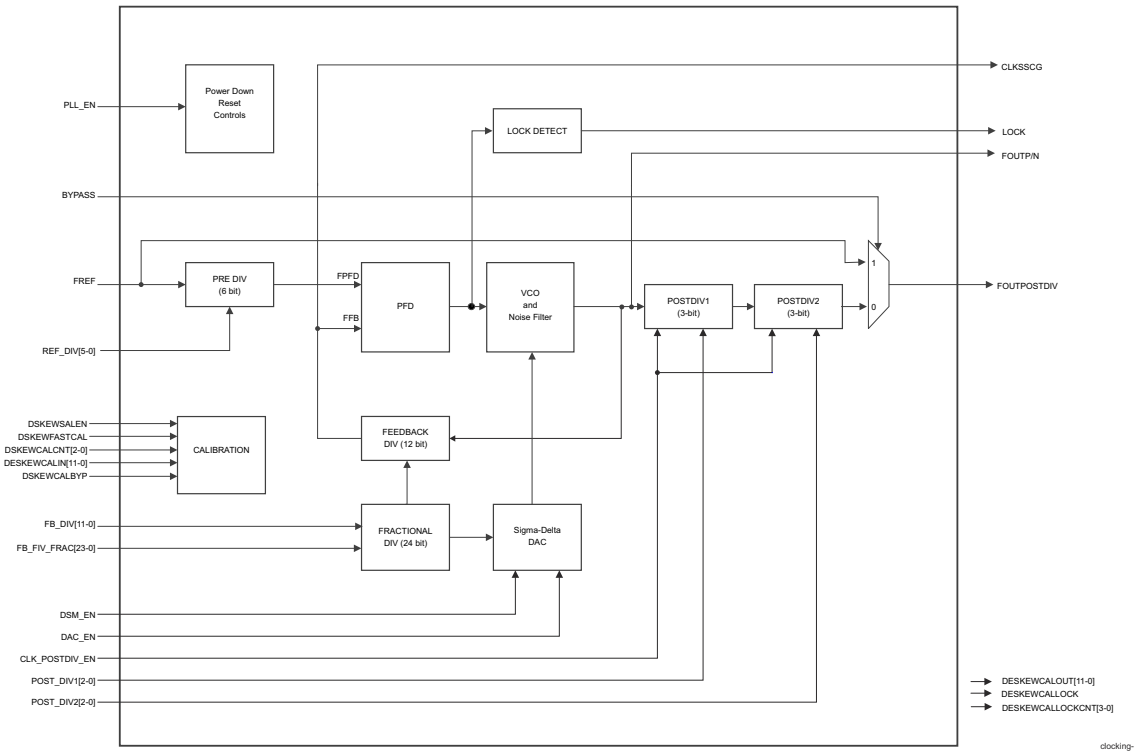

Figure 6-37. Generic PLL Functional Diagram for PLLTS16FFCLAFRACF2 Type

6.4.5.4.1.1 PLLs Input Clocks

As shown in Figure 6-37 the reference clock (FREF) input is used to generate the synthesized clock, but can also be used as the bypass clock for some outputs of the PLL whenever the PLL enters bypass mode. It is mandatory for the PLL clock synthesis.

6.4.5.4.1.2 PLL Output Clocks

6.4.5.4.1.2.1 PLLTS16FFCLAFRACF2 Type Output Clocks

Table 6-41 describes the output clocks of PLLTS16FFCLAFRACF2.

Table 6-41. PLLTS16FFCLAFRACF2 Output Clocks

Output	Description	Frequency
FOUTP	Positive phase VCO output (no post divider)	(FREF / REF_DIV) * (FB_DIV + FB_DIV_FRAC)
FOUTN	Negative phase VCO output (no post divider)	(FREF / REF_DIV) * (FB_DIV + FB_DIV_FRAC)
FOUTPOSTDIV	VCO-divided clock output.	FOUTP / (POST_DIV1*POST_DIV2)

Where:

- REF_DIV is the software-configured division ratio binary value.
- FB_DIV is the software-configured division ratio binary value.
- FB_DIV_FRAC is the software-configured fractional division.
- POST_DIV1 is the software-configured division ratio binary value.
- POST_DIV2 is the software-configured division ratio binary value.

Copyright © 2026 Texas Instruments Incorporated

Note

POST_DIV1 and POST_DIV2 valid values are from 1 to 7. To ensure correct operation, POST_DIV1 must always be programmed to a value equal to or greater than POST_DIV2.

Note

For device-specific information about clock output parameters and synthesized clocks, see Table 6-46 and Table 6-47.

6.4.5.4.1.2.2 PLL Lock

PLL module outputs a lock status signal to indicate that the PLL has achieved frequency lock. When the PLL detects no cycle slips between the feedback clock (FFB) and reference clock FPFD (FREF/ REF_DIV[5-0]) for 128 consecutive cycles, it asserts the lock signal high. When the PLL detects any cycle slip, lock signal will go low and stays low until it detects no cycle slip for 128 consecutive cycles. This lock signal is captured in <PLL_name>_STAT[0] LOCK bit. Software can read this bit to determine if the PLL has achieved frequency lock before selecting the PLL clock through external bypass mux.

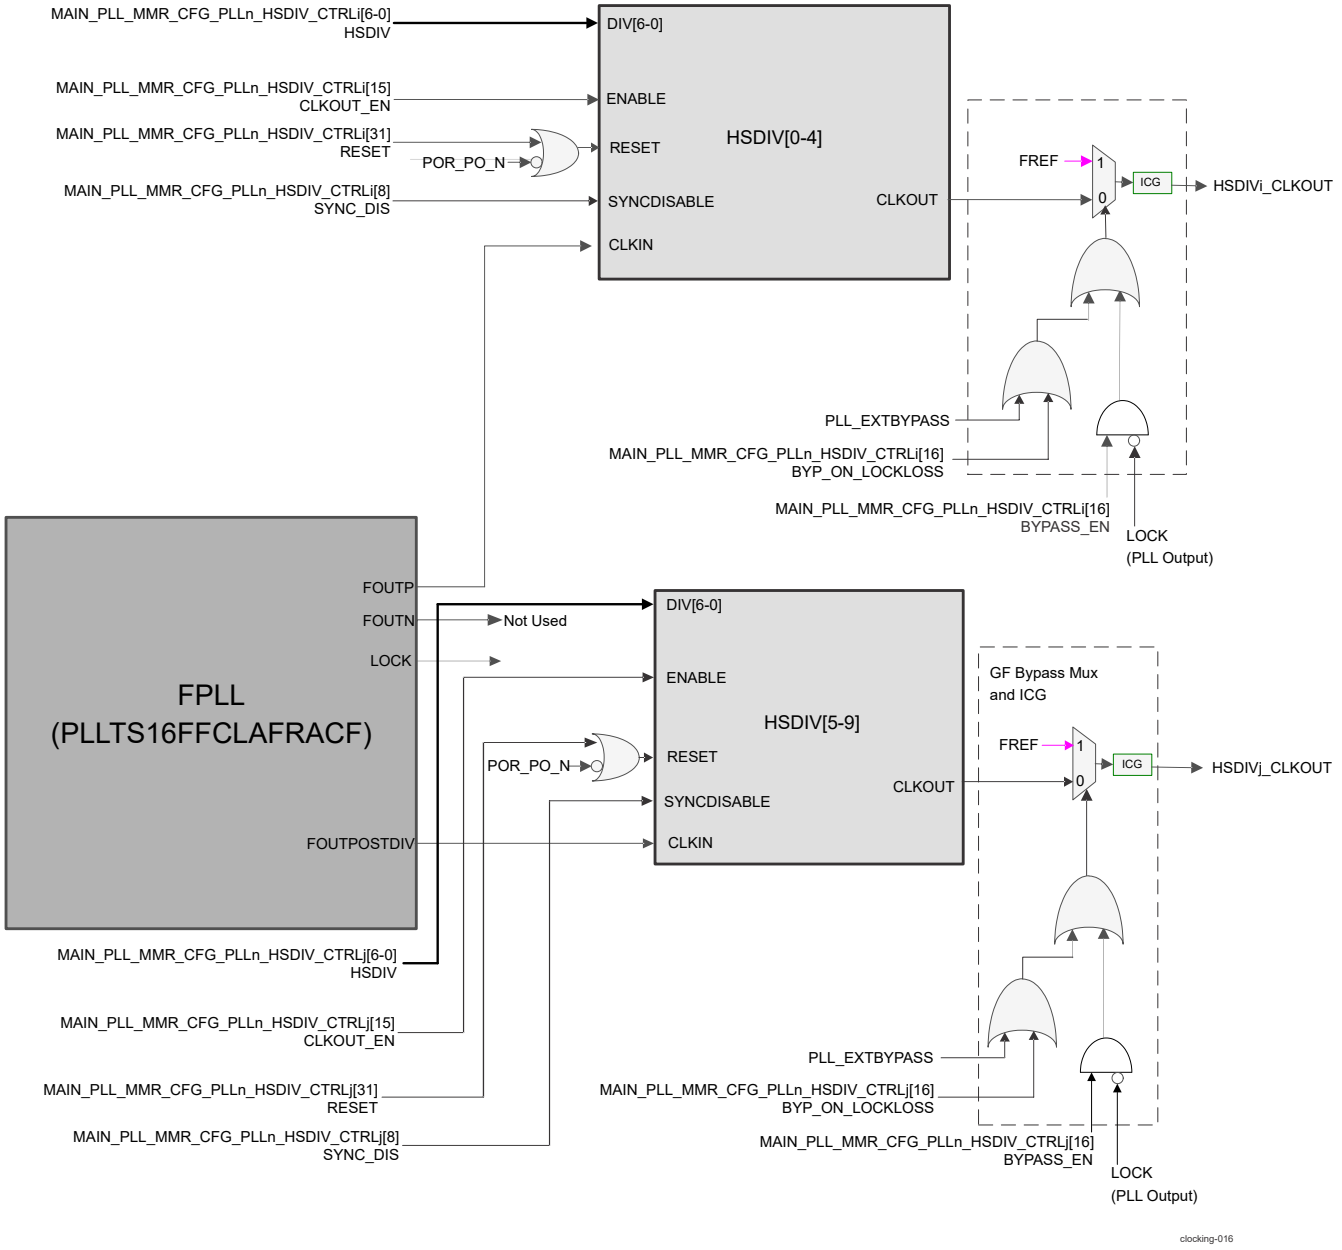
When PLL losses lock, there is a hardware mechanism to automatically bypass the PLL clock to the reference clock (FREF) using the external glitch free mux. BYP_ON_LOCKLOSS bit in <PLL_name>_CTRL register enables this automatic bypass mode on PLL lock loss. When the PLL re-locks, the glitch free mux switches to PLL clock out.

The PLL Lock signal is also routed to ESM module for error reporting. ESM can be configured to generate interrupts to MCU_R5FSS and R5FSS0/1 and assert Low on MCU_ERRORn pin on PLL Lock loss for further action.

6.4.5.4.1.2.3 HSDIVIDER

A PLL may contain up to 10 HSDIVIDER modules to produce more clocks with divided ratio based on the PLL synthesized clock frequency. HSDIVIDER provides only one output. The HSDIVIDER output clock frequency is given by the equations in Table 6-42.

Table 6-42. HSDIV_CLKOUT Frequency With PLL State



Equation	PLL Mode
HSDIV_CLKOUT = FOUTP / (HSDIV + 1)	Locked
HSDIV_CLKOUT = FREF	Before lock or during relock

Where:

- FOUTP is the PLL lock frequency.
- HSDIV is the software-configured division ratio binary value.

Figure 6-38 describes the connection between a HSDIV and a specific type of PLL. Signals related only to this connections are shown in both figures.

Copyright © 2026 Texas Instruments Incorporated

(1) i = 0 to 4; j = 5 to 9

Figure 6-38. PLLTS16FFCLAFRACF2 and HSDIV Connection

6.4.5.4.1.2.4 ICG Module

ICG module ensures that when a particular HSDIV is not enabled the HSDIV clock output is gated off. This is a hardware module with no software control.

6.4.5.4.1.2.5 PLL Power Down

PLLTS16FFCLAFRACF2 is disabled with MCU_PLL_MMR_CFG_PLL0_CTRL[15] PLL_EN or MAIN_PLL_MMR_CFG_PLLn_CTRL[15] PLL_EN.

6.4.5.4.1.2.6 PLL Calibration

PLLTS16FFCLAFRACF2 has calibration feature. The calibration settings are done via <PLL_Name>_CAL_CTRL register. The calibration status can be monitored by reading

Copyright © 2026 Texas Instruments Incorporated

<PLL_Name>_CAL_STAT register. For more information about device-specific information about calibration feature, see Table 6-48.

6.4.5.4.2 PLL Spread Spectrum Modulation Module

Spread Spectrum Modulation (SSMOD) modules on the device reduces Electro Magnetic Interference (EMI). It is a fully-digital circuit, used to modulate the frequency of the selected fractional PLLs. Programming options include selection of center spread or down spread, modulation depth, and modulation shape. The default modulation profile is triangular.

See *Spread Spectrum PLLs* for a list of PLLs that support Spread Spectrum.

SSMOD in the PLL is performed by changing the feedback divider (FRAC and FB_DIV) in a triangular pattern. This varies the frequency of the output clock in a triangular pattern. The frequency of this pattern is the modulation frequency (f_m). It is programmed as a ratio of the CLKIN/4.

Figure 6-39 shows a diagram of the spreading generation block.

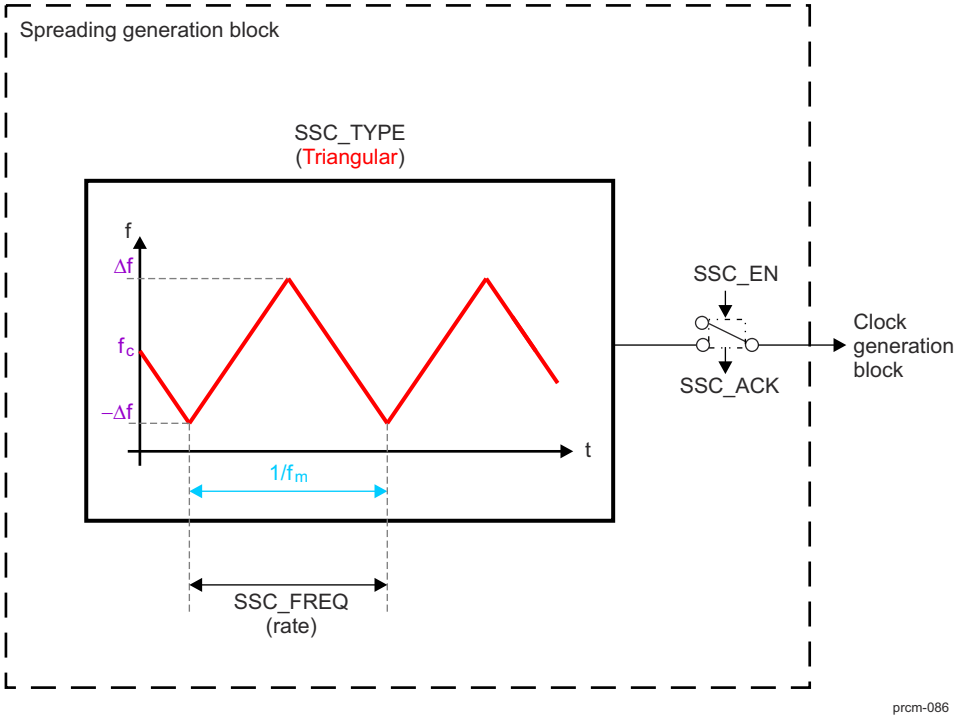


Figure 6-39. Spreading Generation Block Diagram

Note

Δf is the deviation from the center frequency. The total spreading deviation is equal to twice Δf. The peak (ΔM) or the amplitude of the triangular/square pattern as a percent of M would be equal to the percent of the frequency spread (Δf), $\Delta M/M = \Delta f/f_c$.

f_c is the original output clock frequency.

f_m is the spreading frequency.

This additional block generates the required waveform used to reduce EMI. This waveform is then modulated with the initial signal to add some controlled deviation to the clock signal frequency, which spreads the energy of the clock and its harmonics into a band of frequencies, and then reduces EMI. SSMOD_DOWNSPREAD can control the position of the generated signal. It is controlled by the <PLL_name>_CTRL[4] DOWNSPREAD_EN

Copyright © 2026 Texas Instruments Incorporated

bit of the corresponding registers. If the DOWNSPREAD_EN bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0.

The value of SSMOD_FREQ controls the rate of the generated signal. It can be programmed as a ratio of the reference clock: f_{ref} / 4. The value that must be programmed is calculated as follows:
ModFreqDivider = f_{ref} / (4 × f_m), where $f_m < f_{ref} / 70$, $f_{ref} = f_{inp} / (1+N)$, and f_{inp} is the input clock for the PLL.

6.4.5.4.2.1 Definition of SSMOD

The aim of the SSMOD is to add a variation to the frequency of an original clock, which spreads the generated interference over a larger band of frequencies.
In theory, SSMOD means that the clock signal is varied around the desired frequency. For example, for a 1 GHz clock, the frequency might be 999.5 MHz at one time and 1.0005 GHz at another. Doing this constantly causes the power of the tone to be spread out more over a broader band of tight frequencies (centered at the desired tone). To realize this constant variation on the original signal, a modulation with an additional signal (called spreading waveform) is realized.
Creating an SSMOD by spreading the initial clock frequency is done by defining the following parameters:

- The spreading frequency (deviation), which is the ratio of the range of spreading frequency over the original clock frequency.

6.4.5.4.2.2 SSMOD Configuration

Table 6-43 describes the PLL SSMOD control bitfields. Figure 6-40 describes the connection between a SSMOD and a PLL.

Table 6-43. SSMOD related bitfields

Parameter	Register	Description
SSMOD enable control	<PLL_name>n_SS_CTRL[31](1) BYPASS_EN (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[31] BYPASS_EN)	Enable/disable the PLL SSMOD feature.
Wave table maximum address	<PLL_name>n_SS_CTRL[25-18](1) WV_TBL_MAXADDR (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[25-18] WV_TBL_MAXADDR)	Wave table maximum address. Indicates the maximum number of address bits used to access the externalwave table. These bits are not used if <PLL_name>n_SS_CTRL[0] WAVE_SEL = 0
Type of spread	<PLL_name>n_SS_CTRL[4](1) DOWNSPREAD_EN (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[4] DOWNSPREAD_EN)	Selects center spread or down spread clock variance
Wave table selection	<PLL_name>n_SS_CTRL[0] (1) WAVE_SEL (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[0] WAVE_SEL)	Wave pattern select External wave table should only be selected
Modulation dvider	<PLL_name>n_SS_SPREAD[19-16] (1) MOD_DIV (For example, MCU_PLL0 - MCU_PLL0_SS_SPREAD[19-16] MOD_DIV)	Input clock divider. This divider sets the modulation frequency.
Spread Depth	<PLL_name>n_SS_SPREAD[4-0] (1) SPREAD (For example, MCU_PLL0 - MCU_PLL0_SS_SPREAD[4-0] SPREAD)	Sets the spread modulation depth.

Table 6-47. Clock Output Parameter for PLLTS16FFCLAFRACF2 Type (continued)

Clock Output/Divider	Parameter Name	Control/Status Bit Field
Enable fractional noise canceling DAC	Control	<PLL_name>_CTRL[0] DAC_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[0] DAC_EN)

(1) j is the number of HSDIV for the current PLL.

6.4.5.5.4 Calibration Related Bitfields

Table 6-48 lists the calibration related bitfields/bits.

Table 6-48. Recalibration Feature Parameters

Recalibration feture	Parameter Name	Control/Status Bit Field
Calibration enable to actively adjust for input skew	Control	<PLL_name>_CAL_CTRL[31] CAL_EN (For example, PLL12 - PLL12_CAL_CTRL[31] CAL_EN)
Fast calibration enabled	Control	<PLL_name>_CAL_CTRL[20] FAST_CAL (For example, PLL12 - PLL12_CAL_CTRL[20] FAST_CAL)
Calibration loop programmable counter	Control	<PLL_name>_CAL_CTRL[18-16] CAL_CNT (For example, PLL12 - PLL12_CAL_CTRL[18-16] CAL_CNT)
Calibration bypass	Control	<PLL_name>_CAL_CTRL[15] CAL_BYP (For example, PLL12 - PLL12_CAL_CTRL[15] CAL_BYP)
Calibration input	Control	<PLL_name>_CAL_CTRL[11-0] CAL_IN (For example, PLL12 - PLL12_CAL_CTRL[11-0] CAL_IN)
Output of the calibration block	Status	<PLL_name>_CAL_STAT[11-0] CAL_OUT (For example, PLL12 - PLL12_CAL_STAT[11-0] CAL_OUT)

6.4.5.6 PLL Controller (PLLCTRL)

The PLLCTRL manages clock alignment of CBASS clocks to the peripherals in Main and MCU domains. In addition PLLCTRL is also responsible for controlling reset propagation through the chip and providing DFT hooks for testability. Two PLL Controllers are implemented in the device - PLLCTRL0 and MCU_PLLCTRL0. They are respectively related to PLL0 and MCU_PLL0.

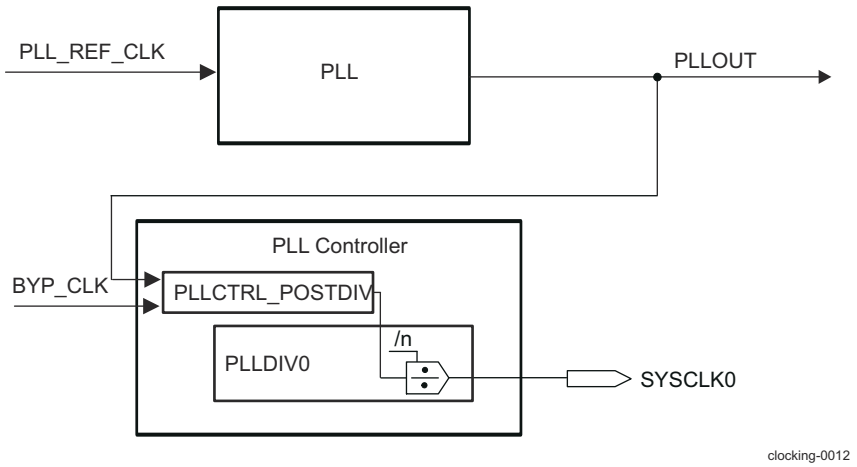

Figure 6-41. PLL Controller

Copyright © 2026 Texas Instruments Incorporated

Note

PLLCTRL_POSTDIV is not supported in this family of devices.

Note

The PLL Controllers registers can be accessed by any controller in the device.

A SYSCLK0 clock out of a PLLCTRL is the only synchronous clock in that domain. That means
- MCU_SYSCLK0 out of MCU_PLLCTRL is the synchronous CBASS clock in MCU domain and
SYSCLK0 out of Main PLLCTRL is the synchronous CBASS clock in Main domain.

6.4.5.7 PLL, PLLCTRL, and HSDIV Controllers Programming Guide

WARNING

PLL register descriptions are provided for debug purposes only. These registers should not be manipulated directly from software. PLL programming and configuration should only be performed using the appropriate APIs provided by TISCI services in TI's Processor Software Development Kits (SDKs). TISCI: Power Management (PM)

6.4.5.7.1 PLL Initialization

6.4.5.7.1.1 Kick Protection Mechanism

Note

PLL configuration registers are write-protected at power-up. Software must first un-lock the PLLn_LOCKKEY0 and PLLn_LOCKKEY1 registers prior to writing to any chip-level registers.

The un-lock process shall follow the steps:

1. Write value 0x68EF3490 to PLLn_LOCKKEY0 register.
2. Write value 0xD172BC5A to PLLn_LOCKKEY1 register.

After these two steps a write access to the PLL registers is allowed. Writing any other data value to either of these two registers locks the kicker mechanism and blocks any writes to the PLL registers.

Note

In order to ensure that all PLL registers are write protected, software must always re-lock the kicker mechanism after completing the register writes.

6.4.5.7.1.2 PLLCTRL Initialization

Note

For validated set of parameters that can be programmed to PLLs, please refer to the device-specific Datasheet.

Initially, the device powers up in PLL bypass mode. The bypass mux is a glitch free mux and is located outside the PLL module. BYPASS_EN bit controls the bypass mux section. During Power-up, the bypass mux defaults to select FREF clock (PLL clock bypass mode).

The following shows the PLL initialization sequence.

1. Wait until supplies are stable and PORz is de-asserted. By this time the reference clock source must be up and running.
2. Default controls settings:

Copyright © 2026 Texas Instruments Incorporated

- By default PLL_EN signal is Low provided by <PLL_name>_CTRL register default state. This signal behaves like a reset control to the PLL.
- By default INTL_BYP_EN signal is low provided by <PLL_name>_CTRL register default state.
- By default BYPASS_EN signal is high provided by PLL MMR CTRL default state. PLL clock will be bypassed externally by a glitch free mux. The output of the mux will be the reference clock FREF.
- LOCK output of PLL will be Low.

3. Program the PLL to a valid setting that runs the VCO within the specified range. The following bits/bitfields must be programmed appropriately by software: DSM_EN, DAC_EN, CLK_POSTDIV_EN, CLK_4PH_EN, REF_DIV[5-0], FB_DIV[11-0], FB_DIV_FRAC[23-0], POST_DIV1[2-0], POST_DIV2[2-0].
4. Wait for 1 µs to allow the PLL internal reset to complete (PLL powerdown switch pulls the loop filter voltage from rail-to-rail, which ensures the PLL will be completely powered down from any state).
5. Assert PLL_EN to a High (by writing a '1' into PLL_EN bit in <PLL_name>_CTRL register).
6. Wait for PLL Lock output to go high. Software can read the LOCK bit in <PLL_name>_STATS register to check if PLL has locked.
7. De-assert BYPASS_EN signal to a Low by writing 0 into BYPASS_EN bit in <PLL_name>_CTRL register.
8. Glitch free mux safely switches to the PLL clock output.

Note

In the case of brown out (supply dips below datasheet minimum) or loss of the reference clock, the state of the PLL will be undetermined. A full reset sequence should be initiated.

Changing PLL setting: During normal operation, before changing PLL settings, the PLL clock must be bypassed by setting BYPASS_EN control to a high. Then follow steps 2 to 8 from the above sequence.

6.4.5.7.1.3 PLL Programming Requirements

- A PLL VCO frequency must be set to > 1500 MHz
  - For best PLL performance, maximize VCO frequency where possible.
- A PLL must always operate in Fractional Mode (DAC_EN and DSM_EN set to ‘1’). This is true even when the FB_DIV is a integer.
- A PLL Reference clock frequency must be > 10 MHz.
- REF_DIV[5:0] must be set to “000001”.
- Calibration procedures for FRACF PLLs in integer mode or fractional mode:
  - **Programming FRACF in Integer Mode with calibration (Static or Auto Calibration)**
    - Set all the common PLL settings (PREDIV, FBDIV, …)
    - DACEN: 0
    - DSMEN = 0 (INT MODE)
    - FASTCAL=1
    - CALBYPASS=0
    - CALCNT[2:0]=2
    - CALIN[11:0]=0
    - CAL_EN=1
    - SET PLL_EN = 1
    - WAIT FOR PLL_LOCK AND CAL_LOCK GO HI
    - CAPTURE AND STORE CALCODE WHEN CAL_LOCK GOES HI IF IT WILL BE USED LATER
    - IF CAL_LOCK times out (> 2 ms) then continue
    - CAL_EN=0 (OPTIONAL, THIS WILL FREEZE CALIBRATION & INTERNAL CALCODE)
  - **Programming FRACF in Fractional Mode (with Static Calcode)**
    - Set all common PLL settings to nearest integer (PREDIV, FBDIV,...)
    - Run calibration as outlined in integer mode
    - CAPTURE AND STORE CALCODE WHEN CAL_LOCK GOES HI IF IT WILL BE USED LATER
    - IF CAL_LOCK times out (> 2 ms) then continue
    - CAL_EN=0 (THIS WILL FREEZE CALIBRATION & INTERNAL CALCODE)
    - IF CAL_LOCK timed out, keep CALBYPASS=0

Copyright © 2026 Texas Instruments Incorporated

- IF CAL_LOCK IS ASSERTED AND CALCODE IS CAPTURED APPLY CALCODE TO CALIN
- CALBYPASS=1 CALCODE IS SET BY CALIN
- ENABLE FRACTIONAL MODE

– **Programming FRACF in Fractional Mode (Auto-Calibration Not Allowed)**

- Set all the common PLL settings (PREDIV, FBDIV, …)
- DACEN=1
- DSMEN=1 (FRAC MODE)
- FASTCAL =X
- CALBYPASS=1 CALCODE IS SET BY CALIN
- CALCNT[2:0]=XX
- CALIN[11:0] = 0 (OR DESIRED CALCODE)
- CAL_EN = 0
- SET PLL_EN = 1
- WAIT FOR PLL_LOCK

PLL Integer mode with Calibration enabled is recommended for applications sensitive to phase noise or jitter: Examples include Refclk for SerDes, PHY, DDR etc. See individual product datasheets for specific SoC requirements. Calibration can be bypassed for digital clocks like ARM. If Calibration is bypassed, CALIN needs to be set to 0.

When Calibration is enabled, PLL Lock time will be longer since SOC needs to wait for CAL_LOCK. Applications sensitive to phase noise must wait for CAL_LOCK to go high.

6.4.5.7.2 HSDIV PLL Programming

<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN = 0 cleanly disables the HSDIV output clock

<PLL_Name>_HSDIV_CTRLk[6-0] HSDIV = <value> for divider

<PLL_Name>_HSDIV_CTRLk[8] SYNC_DIS = 0 insures that the divider changes occur synchronously to the internal divider of the HSDIV block.

when the clock is required,

<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN = 1 cleanly enables the HSDIV output clock

6.4.5.7.3 PLL Controllers Programming - Dividers PLLDIVn and GO Operation

The GO operation is required to change the divider ratios of the PLLDIVn registers. Section 6.4.5.7.3.1, *GO Operation*, discusses the GO operation. Section 6.4.5.7.3.2, *Software Steps to Modify PLLDIVn Ratios*, provides the software steps required to change the divider ratios.

6.4.5.7.3.1 GO Operation

The GO operation writes to the RATIO field in the PLLDIVn. Registers do not change the dividers' divide ratios immediately. The PLLDIV dividers change to the new RATIO rates only during a GO operation. This section discusses the GO operation and alignment of the SYSCLKs.

The PLL Controller clock align control register (ALNCTL) determines which SYSCLKs must be aligned. Before a GO operation, program ALNCTL so that the appropriate clocks are aligned during the GO operation.

A GO operation is initiated by setting the GOSET bit in PLLCMD to 1. During a GO operation:

- Any SYSCLK *n* with the corresponding ALN *n* bit in ALNCTL and SYS *n* bit in DCHANGE set to 1 is paused at the low edge. Then the PLL Controller restarts all these SYSCLKs simultaneously, aligned at the rising edge. When the SYSCLKs are restarted, SYSCLK *n* toggles at the rate programmed in the RATIO field in PLLDIVn.
- Any SYSCLK *n* with the corresponding ALN *n* bit in ALNCTL cleared and the SYS *n* bit in DCHANGE set immediately changes to the new rate programmed in the RATIO field.
- The GOSTAT bit in PLLSTAT is set throughout the duration of a GO operation.

Copyright © 2026 Texas Instruments Incorporated

CAUTION

To help prevent errors, all device operation must be stopped before the GO operation.

6.4.5.7.3.2 Software Steps to Modify PLLDIV Ratios

Perform the following steps to modify PLLDIV.

1. Check that the GOSTAT bit in PLLSTAT is cleared to show that no GO operation is currently in progress.
2. Program the RATIO field in PLLDIVn to the desired new divide-down rate. If the RATIO field changed, the PLL Controller will flag the change in the corresponding bit of DCHANGE.
3. Set the respective ALN *n* bits in ALNCTL to align any SYSCLKs after the GO operation.
4. Set the GOSET bit in PLLCMD to initiate the GO operation to change the divide values and align the SYSCLKs as programmed.
5. Read the GOSTAT bit in PLLSTAT to make sure the bit returns to 0 to indicate that the GO operation has completed.

6.4.5.7.4 Entire Sequence for Programming PLLCTRL, HSDIV, and PLL

Table 6-49 shows the entire sequence of programming PLLCTRL, HSDIV, and PLL from an unknown state to a defined non-spread-spectrum state.

Table 6-49. Programming Sequence of PLLCTRL, HSDIV, and PLL

Step	Description
Unlock PLL registers	<PLL_Name>_LOCKKEY0 (= 0x68EF3490)
	<PLL_Name>_LOCKKEY1 (= 0xD172BC5A)
If PLL0	Configure PLLCTRL block into bypass mode
	PLLCTL[0]PLLEN = 0
	PLLCTL[5] PLLENSRC = 0
Configure external bypass so that no transient clock propagates	<PLL_Name>_CTRL[31] BYPASS_EN = 1
Delay	
Disable HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN =0
Delay	
Disable PLL	<PLL_Name>_CTRL[15] PLL_EN =0
Delay	
Reset HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[31] RESET = 1
If PLL0	Check PLLSTAT[0] GOSTAT to make sure that divider change is not currently in-progress GOSTAT should equal 0.
	Clear GOSET bit PLLCMD[0] GOSET = 0
	Configure divider in PLLCTRL to /1 PLLDIV1 = 0x8000 (enable divider and divide by 1) PLLDIV2 = 0x00 (disable divider and divide by 1)
	Set alignment control bits ALNCTL = 3
	Set GOSET bit to initiate the divider change PLLCMD[0] GOSET = 1
	Check PLLSTAT[0] GOSTAT to make sure that divider change has completed GOSTAT should equal 0.
Configure HSDIV(s) divider value	<PLL_Name>_HSDIV_CTRLk[6-0] HSDIV (=val)
Clear HSDIV(s) SYNC_DIS	<PLL_Name>_HSDIV_CTRLk[8] SYNC_DIS = 0
Delay

Table 6-49. Programming Sequence of PLLCTRL, HSDIV, and PLL (continued)

Step	Description
Clear Reset HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[31] RESET = 0
Configure PLL multiplier	Integer portion of divider <PLL_Name>_FREQ_CTRL0[11-0] (=val) Fractional portion of divider <PLL_Name>_FREQ_CTRL1[23-0] (=val)
Configure PLL dividers	Reference clock divider <PLL_Name>_DIV_CTRL[5-0] REF_DIV = 1
	Post divider 1 <PLL_Name>_DIV_CTRL[18-16] POST_DIV1 = 1
	Post divider 2 <PLL_Name>_DIV_CTRL[26-24] POST_DIV2 = 1
Configure “random” PLL controls	<PLL_Name>_CTRL[8] INTL_BYP_EN = 0
	<PLL_Name>_CTRL[5] CLK_4PH_EN = 0
	<PLL_Name>_DIV_CTRL[26-24] POST_DIV2 = 1
	<PLL_Name>_DIV_CTRL[18-16] POST_DIV1 = 1
	<PLL_Name>_DIV_CTRL[5-0] REF_DIV = 1
	<PLL_Name>_CTRL[1] DSM_EN = 1
	<PLL_Name>_CTRL[0] DAC_EN = 1
	<PLL_Name>_CTRL[4] CLK_POSTDIV_EN – if PLL has more than 5 HSDIV blocks, 1; else 0.
	<PLL_Name>_CTRL[16] BYP_ON_LOCKLOSS (= {0, 1})
Delay	
Enable PLL	<PLL_Name>_CTRL[15] PLL_EN = 1
Wait for Lock	Wait for MCU_PLL0_STAT[0] LOCK = 1
Enable HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN = 1
Delay	
Configure external bypass to pass PLL	<PLL_Name>_CTRL[31] BYPASS_EN = 0
Delay	
If PLL0	Configure PLLCTRL block into PLL mode PLLCTL[0] PLLEN = 0
Lock PLL registers	<PLL_Name>_LOCKKEY0 (= any value)
	<PLL_Name>_LOCKKEY1 (= any value)

6.4.5.7.5 Dual Clock Comparator (DCC)

The Dual Clock Comparator (DCC) is used to determine the accuracy of a clock signal during the time execution of an application. Specifically, the DCC is designed to detect drifts from the expected clock frequency. The desired accuracy can be programed based on calculation for each application. The DCC measures the frequency of a selectable clock source using another input clock as a reference. Internal 12.5 MHz RC oscillator clock is used to validate HFOSC0_CLKOUT. Then HFOSC0_CLKOUT (most accurate clock) is used to validate/track all other clocks in the device. An additional use of this module is to measure the frequency of a selectable clock source, using an external input clock source of known frequency (MCU_EXT_REFCLK0, EXT_REFCLK1 pins). There is one instance of DCC module in MCU domain and seven instances of DCC modules in Main domain to monitor critical clocks. Refer to DCC chapter for details.

7.1 Arm® Cortex®-A53 Subsystem (A53SS)

This section describes the Arm® Cortex®-A53 Subsystem (A53SS) in the device.

Copyright © 2026 Texas Instruments Incorporated

7.1.1 A53SS Overview

7.1.1.1 A53SS Introduction

The SoC implements one cluster of quad-core Arm® Cortex® A53 MPCore™, with 32KB L1 instruction, 32KB L1 data, per core and 512KB L2 shared cache.

The Cortex®-A53 cores are general-purpose processors that can be used for running customer applications.

Note

Notes on references used in this document:
- A53SS is also referred to as Arm® CorePac.
- Cortex®-A53 is often shortened to A53.

The A53SS is built around the Cortex®-A53 MPCore™ (Arm® A53 Cluster), which is provided by Arm and configured by TI. It is based on the symmetric multiprocessor (SMP) architecture, and thus it delivers high performance and optimal power management, debug and emulation capabilities.

The A53 processor is an in-order, 8-stage, dual-issue pipeline with integrated L1 Instruction and Data Caches, compatible with Arm®v8-A architecture. It delivers significantly more performance than its predecessors at a higher level of power efficiency.

The Arm®v8-A architecture brings a number of new features. These include 64-bit data processing, extended virtual addressing and 64-bit general purpose registers. The A53 processor is Arm's first Arm®v8-A processor aimed at providing power-efficient 64-bit processing. It features an in-order, 8-stage, dual-issue pipeline, and improved integer, Arm® Neon™, Floating-Point Unit (FPU) and memory performance.

The A53 CPU supports two execution states: AArch32 and AArch64. The AArch64 state gives the A53 CPU its ability to execute 64-bit applications, while the AArch32 state allows the processor to execute existing Arm®v7-A applications.

7.1.1.2 A53SS Features

The A53SS module supports the following features:

- Quad Core A53 Cluster
  - Full Arm®v8-A Architecture Compliant
    - AArch32 and AArch64 Execution States
    - All exception levels EL0-3
    - A32 Instruction Set (Previously Arm instruction set)
    - T32 instruction set (Previously Thumb instruction set)
    - A64 Instruction Set
  - Data Coherency within Cluster (L1/L2 caches)
  - Advanced SIMD and Floating Point Extensions (Arm® Neon™)
  - Arm®v8 Cryptography Extensions
  - Arm GICv3 architecture
  - In-order pipeline with symmetric dual-issue of most instructions
  - Harvard L1 with system MMU
    - 32 KB Instruction Cache
    - 32 KB Data Cache
  - 512KB Shared L2 Cache
  - Generic Timer(s)
  - Debug
- 128-Bit VBUSM Initiator Interfaces (for axi_r and axi_r channels)
- 128-Bit VBUSM Target Interface (for Accelerator Coherency Port)
- 64-bit Grey-coded system input time
- 48-bit Grey-coded debug input time

Copyright © 2026 Texas Instruments Incorporated

- 48-bit Grey-coded debug input time
- Integrated PBIST controller with BISOR

Note

Some features may not be available. See *Module Integration* for more information.

7.1.2 A53SS Functional Description

7.1.2.1 A53SS Block Diagram

7.1.2.2 Arm Cortex-A53 Cluster

The Arm Cortex-A53 Cluster is provided by Arm and configured by TI. Table 7-1 summarizes the configuration of the Arm Cortex-A53 Cluster on this SoC.

Table 7-1. Arm A53 Cluster Configuration

Parameter	Value
Core Type	A53
Core Revision	r0p4
Number of Cores	4
Bus Width	256
L1 Instruction Cache Size	32K
L1 Data Cache Size	32K
L2 Cache Size	512K
SCU-L2 Cache Protection	Included
Advanced SIMD and Floating Point Extension	Included
Cryptography Extension	Included
CPU Cache Protection	Included
AMBA5 CHI or AMBA4 ACE Interface	AMBA4 ACE (configured for AXI using tie-offs)
Accelerator Coherency Port (ACP)	Included
V7 or v8 Debug Memory Map	v8

Note

For a brief list of features supported by the Arm Cortex-A53 Cluster, see A53SS Features.

For detailed description of the Arm® A53 Cluster, see the *Arm®Cortex®-A53 MPCore™ Processor Technical Reference Manual*.

7.1.2.3 A53SS Interfaces and Async Bridges

The A53SS has the following main interfaces:

- 64-bit graycoded system input time
  - Graycode value provided by Global Timebase Counter (GTC)
  - Dedicated decoder (64-bit input) for graycode-to-binary conversion
- 48-bit graycoded debug input time
  - Graycode value provided by GTC
  - Dedicated decoder (48-bit input) for graycode-to-binary conversion
- 32-bit VBUSP target interface for debug
  - Supported by VBUSP2APB Bridge, which performs VBUSP-to-APB conversion (for controlling the Arm A53 Cluster internal debug logic)
- 32-bit ATB output port for debug/trace
  - Supported by ATB Bridge, which performs clock and voltage level conversion on the combined ATB interface
  - Connected to the Debug Subsystem
- Cross Trigger Interface (CTI) for debug
  - Connected to the Debug Subsystem
- Interface(s) with Arm GIC-500 Interrupt Controller

Copyright © 2026 Texas Instruments Incorporated

  - Supported by GIC AXI Streaming Bridge, which performs clock and voltage level conversion on the AXI streaming protocol
  - Interrupts (PPIs) from Arm A53 Cluster to GIC-500
  - Interrupts (IRQ, FIQ, VIRQ, VFIQ) from GIC-500 to Arm A53 Cluster
- Power/clock interface(s)
  - Dedicated PLL for each Arm A53 Cluster
  - Dedicated LPSC for each Arm A53 Cluster, and also for each A53 core

7.1.2.4 A53SS Interrupts

7.1.2.4.1 A53SS Interrupt Inputs

The A53 CPU recieves interrupts at its inputs (IRQ, FIQ, VIRQ, VFIQ) via the dedicated Arm GIC-500 Interrupt Controller, which resides at the SoC level (MAIN Domain) and is integrated inside the GIC0 Subsystem. The GIC-500 supports all four A53 cores in the system.

The GIC-500 is compliant to the Arm GICv3 standard and supports four types of interrupts:

- *Software Generated Interrupts (SGI)*
  - There are 16 SGIs (ID0-ID15)
  - These are inter-processor interrupts
- *Private Peripheral Interrupts (PPI)*
  - There are 16 PPIs (ID16-ID31)
  - These are wired interrupts dedicated to a specific CPU
  - Many are reserved to specific functions via convention
- *Shared Peripheral Interrupts (SPIs)*
  - There are 256 SPIs (ID32-ID288)
  - These are wired interrupts that can be routed to any core or cluster, based on the programming of that interrupt in the GIC500
- *Locality-Specific Peripheral Interrupts (LPI)*
  - There are 57,344 LPIs
  - These interrupts are used for message-based interrupts from a peripheral

The mapping of PPIs and SPIs to the GIC-500 interrupt inputs can be found in *Interrupts*.

Note

For a brief list of features supported by the GIC-500 module, see the *Interrupts* chapter.

For detailed description of the GIC-500 module, see the *Arm®CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

7.1.2.4.2 A53SS Interrupt Outputs

A53SS Interrupt Outputs lists the interrupts generated by the A53SS.

Table 7-2. A53SS Interrupt Outputs

Interrupt Name (TI)[1]	Interrupt Name (Arm)	Interrupt Description
A53 Core Interrupts (PPIs)[2]		
A53_COREy_VCPUMNTIRQ	VCPUMNTIRQn	This interrupt indicates that a Virtual CPU Interface on the corresponding core needs serviced. This interrupt is serviced by software switching to the virtual CPU and finding what specific service needs done.
A53_COREy_CNTHPIRQ	CNTHPIRQn	This interrupt indicates a physical timer event at the EL2 (Hypervisor) exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL2 and service accordingly.

Copyright © 2026 Texas Instruments Incorporated

Table 7-2. A53SS Interrupt Outputs (continued)

Interrupt Name (TI)(1)	Interrupt Name (Arm)	Interrupt Description
A53_COREy_CNTPNSIRQ	CNTPNSIRQn	This interrupt indicates a physical timer event at the EL1 Non-Secure exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL1 Non-Secure and service accordingly.
A53_COREy_CNTPSIRQ	CNTPSIRQn	This interrupt indicates a physical timer event at the EL1 Secure exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL1 Secure and service accordingly.
A53_COREy_CNTVIRQ	CNTVIRQn	This interrupt indicates a Virtual timer event. Service of this interrupt is dependent on what the timer was set for. Software should take exception and service accordingly.
A53_COREy_PMUIRQ	PMUIRQn	This interrupt is generated by the Performance Monitor Unit (PMU). The PMU can generate an interrupt based on several conditions, depending on programming. Software should take exception and query the PMU as to the cause of the interrupt, and act accordingly.
A53_COREy_DCCIRQ	COMMIRQn	Communications Channel receive or transmit interrupt
A53_COREy_CTIIRQ	CTIIRQn	Cross Trigger Interface interrupt

(1) In this column, *y* is the A53 Core index (0 or 1)
(2) These are 'per core' interrupts

Note

The mapping of these interrupts in the system is summarized in *A53SS Integration*, and can also be found in *Interrupts*.

For more detailed description of these interrupts and their handling, see the *Arm®Cortex®-A53 MPCore™ Processor Technical Reference Manual*.

7.1.2.5 A53SS Power Management and Clocking

7.1.2.5.1 A53SS Power Management

Each Arm A53 Cluster and each A53 CPU reside in a separate power domain, as follows:

There is a dedicated Local Power Sleep Controller (LPSC) for each Arm A53 Cluster, and for each A53 core, as well. The LPSC assignment is as follows:

For more details on these LPSCs, including power-up/down sequences, see *Power*.

7.1.2.5.2 A53SS Clocking

There is a dedicated PLL for each Arm A53 Cluster. The PLL assignment is as follows:

- PLL8 (ARM0 PLL): Dedicated for Arm A53 Cluster 0

For more details on these PLLs, see *Clocking*.

7.1.2.6 A53SS Debug

The A53SS supports the standard Arm debug architecture. Details on Arm debug can be found in the *On-chip Debug* chapter and the relevant Arm specifications.

7.1.2.7 A53SS Global and Debug Timestamps

The A53SS has two timebase input interfaces:

- 64-bit global timestamp: Used for synchronizing the Arm internal timers (via the ARM CNTVALUEB [63:0] bus)
- 48-bit debug timestamp: Can be embedded in Arm trace streams at periodic and strategic locations, allowing the temporal relationship of different trace sources to be determined

Copyright © 2026 Texas Instruments Incorporated

Both of them are fed by the Global Timebase Counter (GTC), which provides a 64-bit graycode value. The A53SS includes two graycode decoders (for global time and debug time, respectively), which take the asynchronous graycoded times, synchronize them to the appropriate clock, and convert them to binary time, as required by Arm.

Note

Both graycode decoders are 64-bit but the one dedicated to debug time has a 48-bit input (the upper 16 bits are tied to 0).

For more details on the GTC, see *Global Timebase Counter (GTC)*.

7.1.2.8 A53SS Watchdog

The A53SS does not have an integrated watchdog timer. Instead, this feature is provided externally by the Real Time Interrupt Module (RTI) module, which implements a windowed watchdog timer capable of issuing warm reset to the SoC, when necessary.

For more details on the RTI windowed watchdog feature, see *Real Time Interrupt Module (RTI/WWDT)*.

7.1.2.9 A53SS Functional Safety - ECC Error Injection Support

In the quad A53 CBA subsystem, there are five ECC aggregators – one for each core and one for the corepac level. Debug domain is not safety critical.

No CBASS/Bridge interconnect safety is supported. Only RAM safety is supported.

The following A53SS ECC Aggregator instances are instantiated:

- A53SS0_ECC_AGGR0: ECC Aggregator for Arm A53 Cluster 0, Core 0
- A53SS0_ECC_AGGR1: ECC Aggregator for Arm A53 Cluster 0, Core 1
- A53SS0_ECC_AGGR2: ECC Aggregator for Arm A53 Cluster 0, Core 2
- A53SS0_ECC_AGGR3: ECC Aggregator for Arm A53 Cluster 0, Core 3
- A53SS0_ECC_AGGR_COREPAC: ECC Aggregator for Arm A53 Cluster 0

7.1.2.9.1 A53 ECC Aggregators During Low Power States

- When a cpu core is in WFI/WFE, the corresponding core ECC Aggregator MMR regions is not accessible and will return error status.
- Similarly when L2 is in WFI, the corepac ECC Aggregator MMR region is not accessible and will return error status.

7.1.2.9.2 Auto-initialization of Memories

All A53 L1 and L2 memory initialization is handled by the Arm core. The TI ECC aggregator is used in inject-only mode and this cannot be used for initialization. The Arm CPU will initialize the cache memories after reset.

There are no other memories in the A53 subsystem beside the cache memories

7.1.2.9.3 A53 SRAM Safety

The Arm A53 Cluster natively supports ECC/parity protection on A53 SRAMs and error injection on few memories. The A53SS adds error injection capability on all internal SRAM. This is a valuable TI addition to the Arm native implementation.

Table 7-3. A53 SRAM Safety Support

RAM	A53 Error Injection Support	TI Error Injection Support
L1 I-Cache Data	No	Single error injection
L1 I-Cache Tag	No	Single error injection
L1 D-Cache Data	Double error injection	Single and double error injection
L1 D-Cache Tag	No	Single error injection
L1 Data Dirty	No	Single error injection

Copyright © 2026 Texas Instruments Incorporated

Table 7-3. A53 SRAM Safety Support (continued)

RAM	A53 Error Injection Support	TI Error Injection Support
TLB RAM	No	Single error injection
SCU Duplicate Tag	No	Single and double error injection
L2 Tag RAM	Double error injection	Single and double error injection
L2 Data RAM	Double error injection	Single and double error injection

The ECC Aggregator for the cores stimulates errors in the following RAMs:

- L1 I-Cache Data RAM
- L1 I-Cache Tag RAM
- L1 D-Cache Data RAM
- L1 D-Cache Tag RAM
- L1 D-Cache Dirty RAM
- TLB RAM
- L1 SCU L1-D Duplicate Tag RAM

The ECC Aggregator for the L2 cache stimulates errors in the following RAMs:

- L2 Data RAM
- L2 Tag RAM

7.1.2.9.4 A53 SRAM ECC Aggregator Configurations

There are several schemas of memory protection employed inside of the processors. The tables below describe the schema and arrangement. This describes what bits are protected, how they are protected, the behavior when an error is detected and what bits can be disturbed for ECC testing purposes. This also lists the RAMID associated with each memory to the corresponding ECC Aggregator.

The key for the protection schemes is as follows:

- Parity – Parity Bit(s) to protect data
- ECC – Error Correction Code to protect Data
- SED – Single Error Detection
- SECDED – Single Error Correction, Double Error Detection
- SEDSEC – Single Error Detection, Single Error Correction

Table 7-4. CPU Memories Safety Details

Memory	Protection	RAM Arrangement	CPU (Core ECC Aggr) Rams Ram ID	Notes
L1 I-Cache Data	Parity SED	41 – Parity for 40:21 40:21 – Instruction 20 – Parity for 19:0 19:0 – Instruction	0-3	Error detection results in both lines being invalidated then refetched from L2 or memory
L1 I-Cache Tag	Parity SED	31 – Parity for 30:0 30:0 – Data	4-5	Error detection results in both lines being invalidated, then line refetched from L2 or memory
L1 D-cache Data	ECC SECDED	38:32 – ECC 31:0 – Data	6-13	Error results in line being cleaned and invalidated from L1 with single bit errors corrected as part of eviction. Line refetched from L2 or memory
L1 D-Cache Tag	Parity SED	30 – Parity for 29:0 29:0 – Tag	14-17	Cache sizes makes LSB unnecessary (always 0) so they are removed from the actual RAM. Error results in line cleaned and invalidated from L1. SCU duplicate tags are used to get the correct address. Line refetched from L2 or memory

Copyright © 2026 Texas Instruments Incorporated

Table 7-4. CPU Memories Safety Details (continued)

Memory	Protection	RAM Arrangement	CPU (Core ECC Aggr) Rams Ram ID	Notes
L1 D-cache Dirty	Parity SEDSEC	11:10 – Way 1/3 Dirty copy 2 and 1. Parity for 4 9:8 – Way 0/2 Dirty copy 2 and 1. Parity for 0 7 – Way 1/3 Outer Allocation Hint 6 – Way 1/3 Age 5:4 – Way 1/3 Partial MOESI 3 – Way 0/2 Outer Allocation Hint 2 – Way 0/2 Age 1:0 – Way 0/2 Partial MOESI	18	Error results in line cleaned and invalidated from L1 with single bit errors corrected as part of the eviction. Only dirty bit is protected. Other bits are just performance hints
TLB	Parity SED	116 – parity for 113:62 115 – Parity for 61:31 114 – Parity for 30:0 113:62 – Page Attributes 61:31 – Entry Identifiers 30:0 – Address	19-22	Error detection results in entry invalidated, new pagewalk to refetch.
SCU L1 Duplicate Tag	ECC SECDED	37:31 - ECC for 30:0 30:0 - Duplicate Tag	23-26 (accessed by each Core's ecc_aggr)	Cache sizes makes LSB unnecessary (always 0) so they are removed from the actual RAM. Corretable Error – Tag rewritten with correct value, access retried Uncorrectable Error – Tag is invalidated

Table 7-5. L2 Memories Safety Details

Memory	Protection	RAM Arrangement	RAM_ID (L2 Cache RAMs)	Notes
L2 Tag	ECC SECDED	37:31 – ECC for 30:0 30:0 - Tag	0-15	Cache sizes makes LSB unnecessary (always 0) so they are removed from the actual RAM. Corretable Error – Tag rewritten with correct value, access retried. Uncorrectable Error – Tag is invalidated
L2 Victim	None	–	–	Performance Hint Only – Error has no functional impact
L2 Data	ECC SECDED	71:64 – ECC for 63:0 63:0 – Data	16-23	Error results in Data corrected inline, access may stall for 1-2 cycles. After correction, line might be evicted
Branch Predictor	None	–	–	Performance Hint Only – Error has no functional impact

7.1.2.10 A53SS Boot

For A53SS boot sequence and any other A53SS boot details, see *Control Module (CTRL_MMR)*.

7.1.2.11 A53SS Interprocessor Communication

The Arm A53 core(s) can communicate with other device cores by supporting interrupt generation to and from these cores. The interprocessor communication (IPC) interrupts are assigned in the corresponding BOOTCFG0 memory-mapped registers (MMRs) called IPC_SETx / IPC_CLRx. For more information, see *Control Module (CTRL_MMR)*.

7.2 Arm Cortex R5F Subsystem (R5FSS)

This chapter describes the Arm Cortex R5F real-time microcontroller unit subsystem (R5FSS) in the device.

7.2.1 R5FSS Overview 538
7.2.2 R5FSS Functional Description 540

Copyright © 2026 Texas Instruments Incorporated

7.2.1 R5FSS Overview

The R5FSS is a dual-core implementation of the Arm® Cortex®-R5F processor configured for split or single-core operation. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm CoreSight™ debug and trace architecture, integrated vectored interrupt manager (VIM), ECC aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

Note

The Cortex-R5F processor is a Cortex-R5 processor that includes the optional floating point unit (FPU) extension. In this TRM, all references to the Cortex-R5 processor apply to the Cortex-R5F processor by default.

7.2.1.1 R5FSS Features

Each R5FSS supports the following features:

- Dual-core Arm Cortex-R5F
  - Core revision: r1p3
  - Armv7-R profile
  - Boot-time configurable to be in single- or dual-core (split) mode
    - Dual-core mode: Two independently operating cores (asymmetric multi processing, no coherence)
    - Single-core mode: Only one operating core (CPU0)
      - CPU0 uses TCM resources of both cores
      - CPU1 caches and interrupts are unused in this mode
  - L1 memory system
    - 32KB instruction cache
      - 4x8KB ways
      - SECDED ECC protected per 64 bits
    - 32KB data cache
      - 4x8KB ways
      - SECDED ECC protected per 32 bits
    - 64KB tightly-coupled memory (TCM) per CPU
      - SECDED ECC protected per 32 bits
      - TCM hard error cache Implemented in CPU
      - Readable/writable from system
      - TCMs initialized (to 0's) at reset
      - Split into A and B banks (with B further splitting into B0 and B1 interleaved banks)
        - 32KB TCMA (ATCM)
        - 16KB TCMB0 (B0TCM)
        - 16KB TCMB1 (B1TCM)
      - In dual-core mode, TCM is 64KB in total (per core):
        - 32KB TCMA
        - 16KB TCMB0 + 16KB TCMB1
      - In single-core mode, TCM is 128KB in total (per core):
        - 64KB TCMA
        - 32KB TCMB0 + 32KB TCMB1
  - Low interrupt latency with restartable instructions
  - Non-maskable interrupt (NMI)
  - Full-precision floating point (VFPv3)
  - 16 region memory protection unit (MPU)
  - 8 breakpoints
  - 8 watchpoints
  - Dynamic branch prediction with global history buffer and 4-entry return stack

Copyright © 2026 Texas Instruments Incorporated

  - CoreSight debug access port (DAP)
  - CoreSight embedded trace macrocell (ETM-R5) interface
  - Performance monitoring unit (PMU)
- Interfaces
  - 64-bit VBUSM initiator pair (1 read, 1 write) for L3 memory accesses (per core)
  - 64-bit VBUSM target for TCM access (per core)
    - Also allows access to cache for debug purposes
  - 32-bit VBUSP initiator for peripheral access (per core)
  - 32-bit VBUSP target configuration port (per core)
  - 32-bit VBUSP target debug port
    - Allows access to all R5FSS internal debug logic
- Synchronous clock domain crossing on all interfaces
  - Both CPU and interface clocks run at the same frequency (1:1 ratio)
- 32-bit to 36-bit region-based address translation (RAT) on memory access initiators
  - 4 regions
    - Base address + size
    - Must be size aligned
- Integrated vectored interrupt manager (VIM)
  - 256 interrupts per core
    - Only interrupts connected to R5F core 0 are available in single-core mode
    - Each interrupt programmable as either IRQ or FIQ
    - Each interrupt has a programmable enable mask
    - Each interrupt has a programmable 4-bit priority
  - Priority interrupt supported
  - Vectored interrupt interface
    - Compatible with R5F VIC port
    - Programmable 32-bit vector address per interrupt
      - Address is SECDED error protected
      - Default vector addresses provided on DED
    - Split or single-core capable
    - Software interrupt generation
- Integrated ECC aggregators
  - Support for error injection to all supported ECC memory blocks to test ECC functionality (add-on function from TI)
  - One ECC aggregator per core to cover all RAMs and caches associated with that core
- Standard Arm CoreSight debug and trace architecture at the R5FSS level
  - Cross triggering: Supported by cross trigger interface (CTI) (per CPU) and cross trigger matrix (CTM) components
  - Processor trace: Supported by embedded trace macrocell (ETM) (per CPU) and advanced trace bus (ATB) funnel components
- Boot
  - From ROM or external memory
  - From TCM

See Section 7.2.2 for a functional block diagram and more details on the R5FSS.

7.2.1.2 R5FSS Not Supported Features

The R5FSS does *not* support the following native R5F features in this device:

- ACP port (no coherence)
- Bus parity / ECC
- Multiple power domains

Copyright © 2026 Texas Instruments Incorporated

7.2.2 R5FSS Functional Description

7.2.2.1 R5FSS Block Diagram

Figure 7-2 shows the R5FSS block diagram.

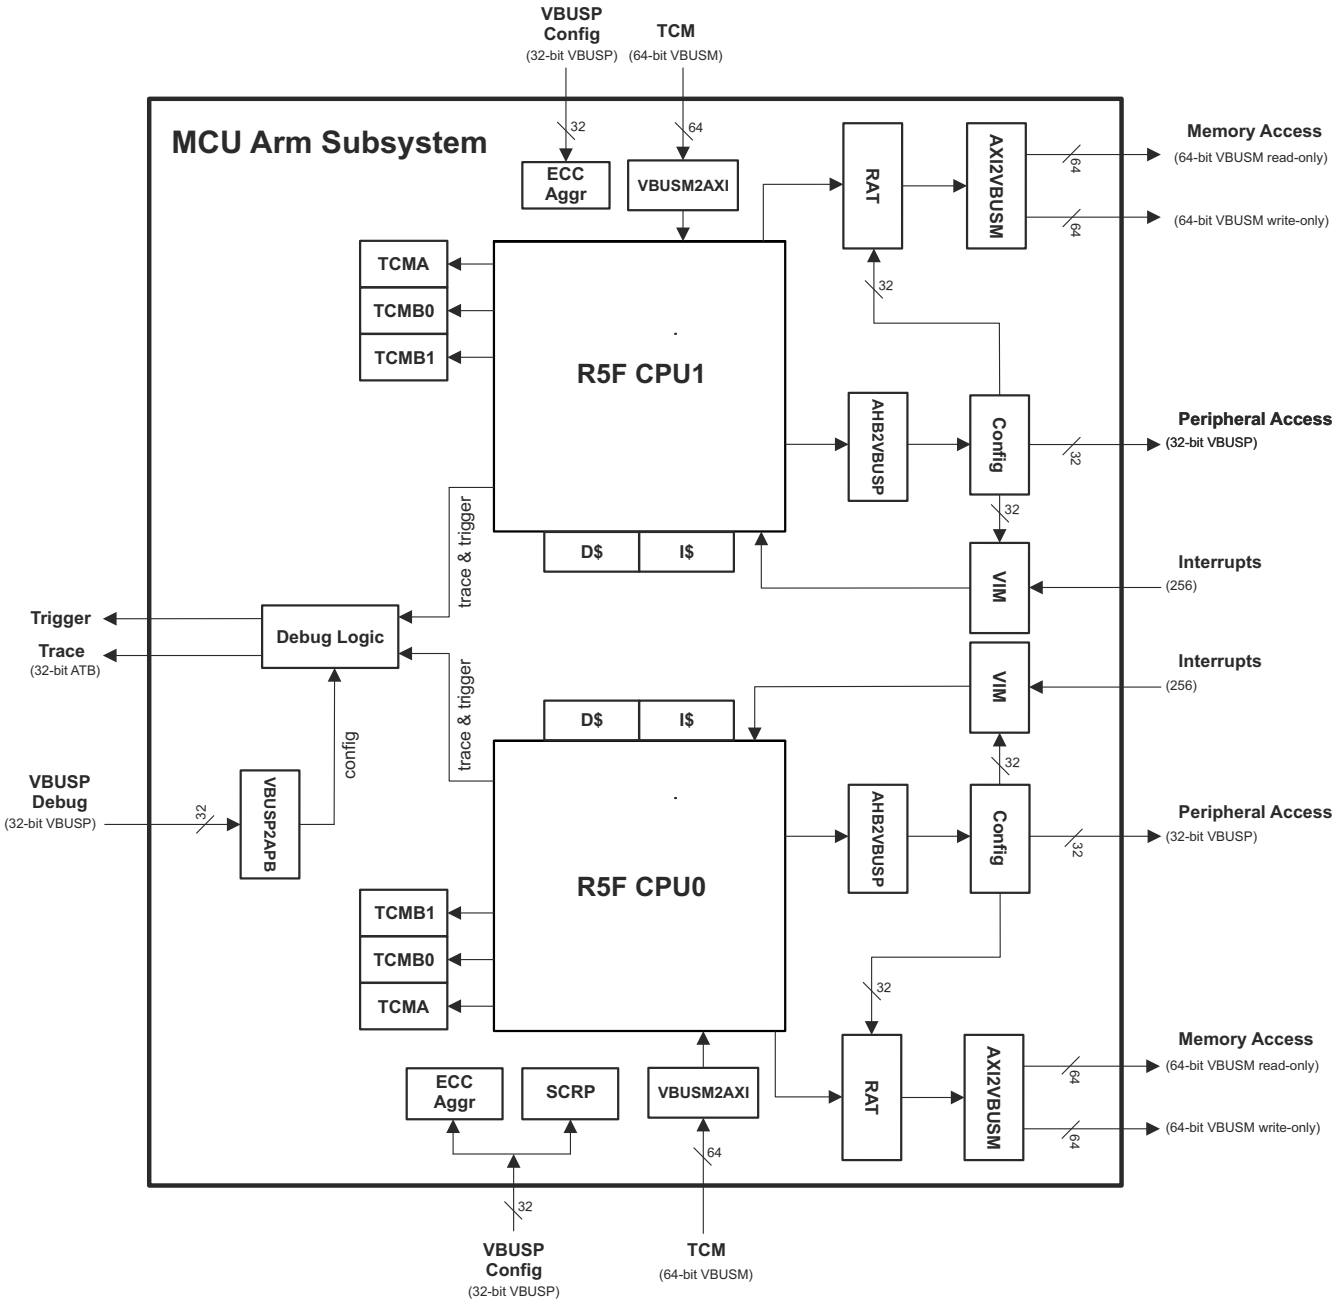

Figure 7-2. R5FSS Block Diagram

7.2.2.2 R5FSS Cortex-R5F Core

The Cortex-R5F is a processor from Arm, which is based on the Armv7-R profile. Each R5FSS implements two R5F cores, CPU0 and CPU1, each with their own RAMs and interfaces. While in reset, they can be bootstrapped to work in one of two modes: split or single-core.

In split mode, each R5F core works completely independent from the other (asymmetric multi-processing, or AMP). Each core uses its own RAMs and interfaces, with no coherence between the two cores. The only

Copyright © 2026 Texas Instruments Incorporated

restriction is that CPU0 must be in a higher power/reset state than CPU1. For instance, CPU1 cannot be out of reset if CPU0 is not.

In single-core mode:

- CPU0 is the only operating core
- CPU1 TCMs are stacked on CPU0 TCMs and are accessible only by CPU0 and CPU0 TCM interface
- The TCM size for CPU0 is essentially doubled in this mode (128KB)
- CPU1 caches and interrupts are not used

For a brief list of features supported by the R5F processor in this device, see Section 7.2.1.1. For more detailed description of this processor, see the *Arm Cortex-R5 Technical Reference Manual*.

7.2.2.2.1 L1 Caches

The R5F has a Harvard cache architrecture, which means it has an independent L1 instruction cache (16KB) and L1 data cache (16KB). The instruction cache is protected by SECDED ECC per 64 bits. The data cache is protected by SECDED ECC per 32 bits.

7.2.2.2.2 Tightly-Coupled Memories (TCMs)

The R5F has two tightly-coupled memories (TCMs), ATCM and BTCM. The BTCM is further broken down into two interleaved banks, B0TCM and B1TCM.

TCMs are low-latency, tightly integrated memories for the R5F to use. Either TCM can be used for any combination of instruction and/or data. TCM performance is equal to performance on instructions/data that are in cache. However, TCMs have some additional advantages over cache. TCMs can be loaded with instructions that do not cache well (such as ISRs) or preloaded with code by an external source, before that code is needed, to save cache miss time. TCMs are also a good place for blocks of data for intense processing. They can be loaded (or pre-loaded by an external source) before the data is needed, saving cache miss time. The data can then be directly accessed by an external source, instead of needing to do cache evicts.

As mentioned, TCMs can be accessed (either read or written) by an external source over the TCM VBUSM target interface. This allows instructions or data to be preloaded, or for data to be read out after the R5F has processed it. The VBUSM target has a lower priority to accessing TCMs than the R5F but care must be taken to keep an external source from reading or writing TCM data that the R5F is working on. This handshaking is external to any of the R5FSS hardware.

TCMs are protected by ECC per 32 bits. For this to work, ECC must be enabled before data is written in to the TCMs (either externally or from the R5F). ECC is enabled via the following R5F system control bits: ACTLR.ATCMPCEN, ACTLR.B0TCMPCEN, and ACTLR.B1TCMPCEN, respectively.

Whether or not the TCMs are enabled is controlled by the ENABLE bit in the corresponding ATCM/BTCM region register. The default (reset) value of this bit is determined by the CPUn_INITRAMA and CPUn_INITRAMB bootstraps, respectively. Both ATCM and BTCM are configured for a size of 32KB in this device. Note that the BTCM size is the total of both B0TCM and B1TCM (16KB each).

If a TCM is not enabled, then it does not appear in the R5F's memory view, but it can be accessed by an external source. If a TCM is enabled, then its place in the R5F memory map is determined by a combination of bootstrap signal and system register. If the CPUn_LOCZRAMA bootstrap signal is high, then the initial base address of ATCM is 0x0000_0000 and the initial address of BTCM is 20'h41010. If the CPUn_LOCZRAMA bootstrap signal is low, then the initial base address of BTCM is 0x0000_0000 and the initial base address of ATCM is 20'h41010.

Copyright © 2026 Texas Instruments Incorporated

Note

This base address of 0x41010 for ATCM/BTCM based on the CPUn_LOCZRAMA bootstrap only affects the R5F's memory view. The SoC will see the ATCM/BTCM based on the TCM target interface regions, as defined in Section 7.2.2.3.2. The base address of either TCM may be overwritten via the ATCM or BTCM region register. Care must be taken not to move the base address of a TCM when it may be being accessed.

It is possible to preload a TCM with instructions and boot from it. See Section 7.2.2.11 for details on TCM booting.

7.2.2.2.3 R5FSS Special Signals

Table 7-6 through Table 7-7 list some R5FSS features associated with special signals.

Table 7-6. R5FSS0 Special Features

Feature	Comment
Cluster affinity group ID	R5F Cluster 0 (ID = 0x0)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
Dual- or single-core mode 0 = Dual mode 1 = Single mode	Controlled via MAIN_SEC_MMR register setting. Defaults to a value defined by eFuse
CPUn execution halt when coming out of reset (CPUn_HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPUn exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPUn VIM base address	0x2FFF_0000
CPUn RAT base address	0x2FFE_0000
CPUn RAT accesses ID	0x4 (CPU0); 0x5 (CPU1)
CPUn ATCM enable at reset (CPUn_INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPUn BTCM enable at reset (CPUn_INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPUn A/BTCM reset base address indicator (CPUn_LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPUn non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPUn VBUSM peripheral port enabled at reset	Enabled
CPUn VBUSP peripheral port enable at reset	Enabled
CPUn VBUSP peripheral port base address	Mapped to 0x0_2000_0000 for low latency MAIN peripherals
CPUn VBUSP peripheral port size	64MB for MAIN peripherals (0x0_2000_0000 to 0x0_2FFF_FFFF)
CPUn VBUSM normal peripheral port base address	Not used
CPUn VBUSM normal peripheral port size	Not used
CPUn VBUSM virtual peripheral port base address	Not used
CPUn VBUSM virtual peripheral port size	Not used
CPUn clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPUn WFI state	Status logged into MAIN_SEC_MMR register bit
CPUn WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

Table 7-7. R5FSS1 Special Features

Feature	Comment
Cluster affinity group ID	R5F Cluster 1 (ID = 0x1)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
Dual- or single-core mode 0 = Dual mode 1 = Single mode	Controlled via MAIN_SEC_MMR register setting. Defaults to a value defined by eFuse
CPUn execution halt when coming out of reset (CPUn_HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPUn exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPUn VIM base address	0x2FFF_0000
CPUn RAT base address	0x2FFE_0000
CPUn RAT accesses ID	0x6 (CPU0); 0x7 (CPU1)
CPUn ATCM enable at reset (CPUn_INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPUn BTCM enable at reset (CPUn_INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPUn A/BTCM reset base address indicator (CPUn_LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPUn non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPUn VBUSM peripheral port enabled at reset	Enabled
CPUn VBUSP peripheral port enable at reset	Enabled
CPUn VBUSP peripheral port base address	Mapped to 0x0_2000_0000 for low latency MAIN peripherals
CPUn VBUSP peripheral port size	64MB for MAIN peripherals (0x0_2000_0000 to 0x0_2FFF_FFFF)
CPUn VBUSM normal peripheral port base address	Not used
CPUn VBUSM normal peripheral port size	Not used
CPUn VBUSM virtual peripheral port base address	Not used
CPUn VBUSM virtual peripheral port size	Not used
CPUn clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPUn WFI state	Status logged into MAIN_SEC_MMR register bit
CPUn WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

7.2.2.3 R5FSS Interfaces

7.2.2.3.1 Initiator Interfaces

The R5FSS has several initiator interfaces per core:

- 64-bit VBUSM initiator pair (1 read – “RMST”, 1 write – “WMST”) for L3 memory accesses; this is the main memory interface
  - Includes region-based address translation (RAT)
- 32-bit VBUSP initiator “PMST” for peripheral access
  - Includes logic that provides the R5F CPU with a private access to VIM and RAT
  - Enabled at reset

Copyright © 2026 Texas Instruments Incorporated

7.2.2.3.2 Target Interfaces

The R5FSS has several target interfaces that define its internal memory space:

- 32-bit VBUSP configuration target (per core)
  - Region [0]: ECC aggregator block
- 64-bit TCM target (per core)
  - Region [0]: ATCM
  - Region [1]: BTCM
  - Region [2]: Instruction cache RAMs
  - Region [3]: Data cache RAMs
- 32-bit VBUSP debug target
  - Provides access to all R5FSS internal debug logic

Regions [0] and [1] of the TCM target interface provide direct access to the TCM RAMs. Access to the RAMs is arbitrated with access from the R5F's L1 memory system. Excessive access while the R5F is also attempting access will degrade performance.

Regions [2] and [3] of the TCM target interface provide access to the cache RAMs for testing purposes. Access to the cache RAMs can only be done while the caches are disabled and should only be done for test purposes.

In addition to the target interfaces, there are peripherals (RAT and VIM) that are only accessible by the R5F. The R5F has an access to these modules via the VBUSP peripheral interface.

7.2.2.4 R5FSS Power, Clocking and Reset

7.2.2.4.1 R5FSS Power

The following R5FSS power considerations should be noted:

- R5FSS has a single power domain for all its internal logic
- When operating in split mode, CPU0 must be in a higher power/reset state than CPU1.

For more details on R5FSS power management, including power-up and power-down sequences, see *Power*.

7.2.2.4.2 R5FSS Clocking

The R5FSS has four clock inputs:

- CPU0_CLK: This is the clock for CPU0 logic
- CPU1_CLK: This is the clock for CPU1 logic
- CPU0_ICLK: This is the clock for CPU0 interfaces
- CPU1_ICLK: This is the clock for CPU1 interfaces

CPU0_CLK and CPU1_CLK are the clocks for all of the internal CPU logic, while CPU0_ICLK and CPU1_ICLK are the clocks for all of the interfaces for their associated CPU (for example: VBUSM and VBUSP bridges, exception generation, debug and trace logic). CPU1 clocks are automatically gated in single-core mode.

The interface clock is an integer ratio of the CPU clock. The exact ratio for this device is 1:1.

7.2.2.4.3 R5FSS Reset

The R5FSS has four reset inputs:

- CPU0_RST: This is the reset for the non-debug logic of CPU0
- CPU0_DBG_RST: This resets the CPU0 debug logic, excluding the APB interface
- CPU1_RST: This is the reset for the non-debug logic of CPU1
- CPU1_DBG_RST: This resets the CPU1 debug logic, excluding the APB interface

In addition to the reset signals, there are two halt signals:

- CPU0_HALT
- CPU1_HALT

Copyright © 2026 Texas Instruments Incorporated

These halt signals keep the CPUs from fetching instructions when they come out of reset. The main use is to have the CPUs halted until the TCMs are loaded (when booting from TCM), though halt could be used for any other purpose.

7.2.2.5 R5FSS Vectored Interrupt Manager (VIM)

7.2.2.5.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU(s). It can be used in either split or single-core configuration.

The VIM module supports the following features:

- 256 interrupt inputs per R5F core
- Each interrupt has its own 4-bit programmable priority
  - Defined via the R5FSS_VIM_PRI_INT_j register
  - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
  - Interrupt enable is done via the R5FSS_VIM_INTR_EN_SET_j register
  - Interrupt disable is done via the R5FSS_VIM_INTR_EN_CLR_j register
- Each interrupt can be programmed as either an IRQ or FIQ
  - Defined via the R5FSS_VIM_INTMAP_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
  - Defined via the R5FSS_VIM_VEC_INT_j register
  - Protected with SECDED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
  - Compatible with R5F VIC port
- Default vector provided when a double-bit error is detected
- Split or single-core capable
  - In single-core mode, only interrupts connected to VIM interrupt core 0 are available
- Software interrupt generation

7.2.2.5.2 VIM Interrupt Inputs

The VIM supports 256 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the two R5F cores can be found in *Interrupt Sources*.

7.2.2.5.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- *CoreN_IRQn*: This is a normal interrupt for core *N* (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the R5FSS_VIM_INTMAP_j register) and is enabled (via the R5FSS_VIM_INTR_EN_SET_j register), then it will cause an IRQ to assert
- *CoreN_FIQn*: This is a fast (or non-maskable) interrupt for core *N* (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

7.2.2.5.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (R5FSS_VIM_VEC_INT_j). Hence, the interrupt vector table is organized in 256 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

Copyright © 2026 Texas Instruments Incorporated

Note

The lower two bits of the 32-bit interrupt vector are always 0s.

Figure 7-3 shows the VIM RAM interrupt vector map.

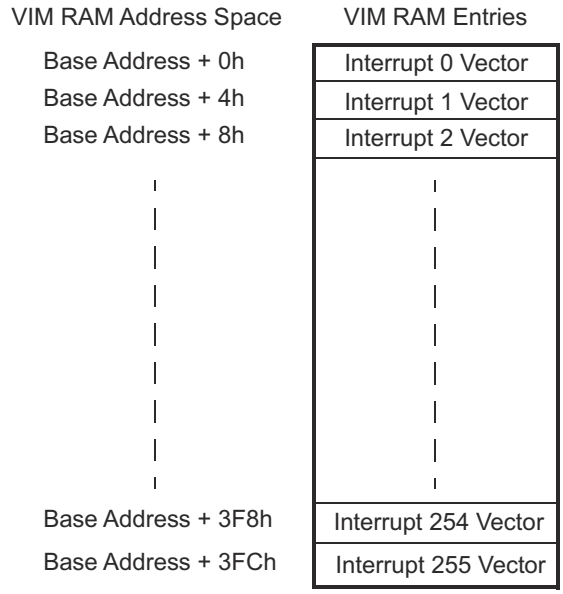

Figure 7-3. VIM RAM Interrupt Vector Map

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. See Table 7-8 for the VIM RAM ID in the ECC aggregator map.

7.2.2.5.5 VIM Interrupt Prioritization

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the R5FSS_VIM_FIQVEC register; IRQ: reading the R5FSS_VIM_IRQVEC register, or the *coreN_IRQACK* going high), then the interrupt is loaded into the corresponding active register (R5FSS_VIM_ACTFIQ / R5FSS_VIM_ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to the R5FSS_VIM_FIQVEC register, or R5FSS_VIM_IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. If the CPU switches this interrupt to active (by reading the R5FSS_VIM_FIQVEC / R5FSS_VIM_IRQVEC register), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by reading the R5FSS_VIM_FIQVEC / R5FSS_VIM_IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the R5FSS_VIM_ACTFIQ / R5FSS_VIM_ACTIRQ register, so that software may continue where it left off.

7.2.2.5.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the R5FSS_VIM_DEDVEC register is used to provide the default vector for the *coreN_IRQADDRV* signal, the R5FSS_VIM_IRQVEC register, and the R5FSS_VIM_FIQVEC register. The R5FSS_VIM_DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
   a. Potentially switch to a completely software interrupt handler in the mean time

Copyright © 2026 Texas Instruments Incorporated

2. Restart the application from scratch
3. Reset the device
4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt . This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by the R5FSS ECC aggregator.

7.2.2.5.7 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

7.2.2.5.8 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in Section 7.2.2.5.8.1, but the procedures in Section 7.2.2.5.8.2 or Section 7.2.2.5.8.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

For FIQs, it is recommended to use the procedure in Section 7.2.2.5.8.4, but the procedure in Section 7.2.2.5.8.5 may be used as an alternative.

Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

7.2.2.5.8.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
   a. CPU asserts *coreN_IRQACK* high
   b. VIM asserts *coreN_IRQADDRV* to indicate that the *coreN_IRQADDR* bus is stable with the correct vector address
   c. CPU reads *coreN_IRQADDR*, jumps to that address, and de-asserts *coreN_IRQACK* low
   d. VIM de-asserts *coreN_IRQn* and *coreN_IRQADDRV*, VIM masks (discards) all IRQs with the same or lower priority
   e. VIM loads the value from the R5FSS_VIM_PRIIRQ[9:0] NUM bit field (which corresponds to the vector address) into the R5FSS_VIM_ACTIRQ[9:0] NUM bit field, which causes the R5FSS_VIM_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS_VIM_ACTIRQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS_VIM_INTTYPE_j register to determine type)
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_IRQSTS_j register, or R5FSS_VIM_STS_j register

Copyright © 2026 Texas Instruments Incorporated

ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt

b. Level
   i. Clear the interrupt at the source
   ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_IRQSTS_j register, or R5FSS_VIM_STS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt

4. Write any value to the R5FSS_VIM_IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTIRQ[31] VALID bit

7.2.2.5.8.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the R5FSS_VIM_IRQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN_IRQn* will re-assert, allowing priority interruption of an interrupt
   b. Reading this register will cause the value from the R5FSS_VIM_PRIIRQ[9:0] NUM bit field to be loaded into the R5FSS_VIM_ACTIRQ[9:0] NUM bit field, and the R5FSS_VIM_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
      ii. Clear the interrupt at the source

   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register

4. Write any value to the R5FSS_VIM_IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTIRQ[31] VALID bit

7.2.2.5.8.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the R5FSS_VIM_IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS_VIM_IRQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the R5FSS_VIM_PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
   b. Optionally read the R5FSS_VIM_IRQGSTS register to determine which groups have IRQs pending, then read the R5FSS_VIM_IRQSTS_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt

Copyright © 2026 Texas Instruments Incorporated

3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
      ii. Clear the interrupt at the source.
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register

7.2.2.5.8.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the R5FSS_VIM_FIQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN_FIQn* will re-assert, allowing priority interruption of an interrupt.
   b. Reading this register will cause the value from the R5FSS_VIM_PRIFIQ[9:0] NUM bit field to be loaded into the R5FSS_VIM_ACTFIQ[9:0] NUM bit field, and the R5FSS_VIM_ACTFIQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS_VIM_ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS_VIM_INTTYPE_j register to determine type)
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register
      ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS_VIM_FIQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTFIQ[31] VALID bit

7.2.2.5.8.5 Servicing FIQ (Alternative)

If a user does not want to use the R5FSS_VIM_FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS_VIM_FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the R5FSS_VIM_FIQVEC register to determine which interrupt is the highest priority FIQ currently asserted, OR

Copyright © 2026 Texas Instruments Incorporated

b. Optionally read the R5FSS_VIM_FIQGSTS register to determine which groups have IRQs pending, then read the R5FSS_VIM_FIQSTS_j register and use a software prioritization scheme to determine which FIQ to service

2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register
      ii. Clear the interrupt at the source.
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register.

7.2.2.6 R5FSS Region Address Translation (RAT)

The R5F is a 32-bit processor, which means it can only access 4GB of directly addressable memory. The R5FSS includes a region-based address translation (RAT) unit per core, which allows the R5F to access higher address ranges. The R5FSS RAT module translates a 32-bit input address into a 36-bit output address. It supports 4 regions. For more details on RAT functionality, refer to *Region-based Address Translation (RAT) Module*.

7.2.2.7 R5FSS ECC Support

The R5F provides native ECC and parity support on all related memories, generating and checking the redundancy automatically. The methods for checking and reporting errors are available in the *Arm Cortex-R5 Technical Reference Manual*.

The R5FSS adds the capability of testing this logic by allowing errors (single and double bit) to be injected into memories (for testing purposes) via an ECC aggregator (per core). Note that because the R5FSS ECC aggregator is only used in error-injection mode, it only supports a subset of the generic ECC aggregator functionality in the device.

For a detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of R5FSS CPU0 and CPU1 ECC aggregators, see *R5FSS_CPU0_ECC_AGGR_CFG_REGS Registers* and *R5FSS_CPU1_ECC_AGGR_CFG_REGS Registers*, respectively.

Table 7-8 provides the RAM ID for each core. This is needed for bit field [10-0] ECC_VECTOR in the corresponding R5FSS_CPU0_VECTOR / R5FSS_CPU1_VECTOR register (part of the ECC aggregator register space).

Table 7-8. RAM ID Map for ECC Aggregator (Per Core)

RAM ID	Memory Name
0	CPU0/1 ITAG RAM0
1	CPU0/1 ITAG RAM1
2	CPU0/1 ITAG RAM2

7.2.2.8 R5FSS Memory View

The memory view of each R5F (that is, the memory map as seen by each R5F) is a function of several things:

- Exception vector bootstrap: The R5F exception table (including boot vector) is always 32 bytes at address 0x00000000 as seen by the R5F. If not booting from a TCM, then boot is done over the main memory interface. The exception vector bootstrap is under software control, which allows these 32 bytes at address 0x00000000 to be remapped somewhere else in the SoC memory map.
- TCM locations: TCMs can be enabled or disabled and located at different places in the memory map, depending on bootstrap configuration. For more details, see Section 7.2.2.2.2.
- Peripheral interface locatons: The RF5 natively supports three interfaces for peripheral access. Each can be enabled/disabled and located based on bootstrap configuration. Note that the VBUSP peripheral interface must be enabled in order to use RAT and VIM.
- RAT base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- VIM base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- RAT programming: The RAT can take regions of memory accessible by the main memory interface and map them to different addresses.

The combination of the above determines what the R5F sees where in the memory map, and over what interface different transactions come out. Every transaction that does not directly address a TCM or a peripheral interface comes over the main memory interface. Transactions on the main memory interface can be further remapped with the RAT.

See *Memory Map*, for the complete R5F memory view for this device.

7.2.2.9 R5FSS Interrupts

All interrupts that are generated by the R5FSS are summarized in *R5FSS0/1 Hardware Requests*, along with their mapping. They can be divided into the following groups:

- R5F CPU internal interrupts: These are described in *Arm Cortex-R5 Technical Reference Manual*.
- ECC aggregator interrupts: These are described in the *ECC Aggregator* chapter.

Copyright © 2026 Texas Instruments Incorporated

- RAT exception interrupt.

Interrupt outputs: FPIXCm, FPUFCm, FPOFCm, FPDZCm, FPIDCm, and FPIOCm from R5F are not connected. Consequently, the only way to check the status of the cumulative exception status flags is by reading the FPSCR register.

7.2.2.10 R5FSS Debug and Trace

The R5FSS supports standard Arm CoreSight debug and trace architecture. For more details, see the *On-chip Debug* chapter.

7.2.2.11 R5FSS Boot Options

There are two methods of booting the R5F, or rather, two methods of placing the exception vectors (of which the boot vector is one).

The first method is to have the exception vectors external to the R5F. The user can place the exception vectors at the address indicated by the exception vector bootstrap and then program the boot vector there. When the processor exits reset, it will fetch the boot vector from this location.

The second method is to boot from a TCM. To do this, software should take the following steps:

1. Assert the correct bootstraps
   a. To boot from ATCM, set CPUn_INITRAMA (or CPUn_INITRAMB to boot from BTCM)
   b. Assert CPUn_LOCZRAMA properly for the desired TCM
2. Assert CPUn_HALT
3. Release the CPU from reset
4. Load the desired code into the TCM via the TCM target port
   a. Exception vectors should be located at address 0x00000000 of the TCM
5. De-assert CPUn_HALT

7.2.2.12 R5FSS Core Memory ECC Events

The R5F core generates several events as part of event bus that can be monitored by the PMU for debugging. The memory ECC related events from the event bus are exported to ESM for monitoring.

There are four ECC interrupts to the ESM that aggregate different categories of ECC events – CPU0 single error, CPU0 multi error, CPU1 single error, and CPU1 multi error events. Each ECC event has a 2-bit event bus counter associated with it. Everytime an event occurs, the counter is incremented by 1 till it reaches the max value of 3. The interrupt is asserted if the bus counter of any event associated with the interrupt is non-zero.

Each event bus counter has a MMR decrement control to decrement the counter by 1. So, for example, if a counter value is 2, the MMR to decrement the counter would need to be written 2 times to decrement the counter to 0. The reason decrement control has been added instead of clear control is if a new error occurs between the time the status register is read and the clear MMR is written, the new error would be lost. Write-to-decrement ensures that this does not happen.

When all event bus counters of an associated interrupt are zero, the interrupt is cleared. It takes three clock cycles for the event bus counter to be decremented once the write to the decrement control MMR presents itself at the R5FSS boundary.

Since each of the four ECC interrupts have single bit control to set the interrupt but multiple bits for clearing it, note that once an interrupt is set using the R5FSS_EVNT_BUS_ESM_SET register, it can be cleared by setting all the bits of the R5FSS_EVNT_BUS_ESM_CLR register that correspond to that particular interrupt. For example, if bit [0] of the R5FSS_EVNT_BUS_ESM_SET register is set, it can be cleared by setting bits [7-0] of the R5FSS_EVNT_BUS_ESM_CLR register to clear the interrupt.

The R5 core event bus only signals event when it is enabled. Non-invasive or invasive debug mode needs to be enabled to enable the PMU counters.

Copyright © 2026 Texas Instruments Incorporated

The export of the events to the event bus can be enabled by setting the X bit in the Performance Monitor Control Register of the R5 core. For more details, refer to Arm R5 TRM.

Table 7-9. R5 Event Bus Single-Bit Error Events

Event Bus Bit #	Description	Associated Status Register
22	Instruction cache tag RAM parity or correctable ECC error.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS0 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS0
23	Instruction cache data RAM parity or correctable ECC error.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS1 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS1
24	Data cache tag or dirty RAM parity error or correctable ECC error, from data-side or ACP.	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS2 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[0] EVNT_BUS2

39	B1TCM multi-bit ECC error.	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS6 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[0] EVNT_BUS6

7.3 Cortex R5F Subsystem (R5FSS)

This chapter describes the Arm Cortex R5F real-time microcontroller unit subsystem (R5FSS) in the device.

7.3.1 R5FSS Overview

The R5FSS is a single-core implementation of the Arm® Cortex®-R5F processor that acts as the Device Manager responsible for boot, resource management, and power management functions. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm CoreSight™ debug and trace architecture, integrated vectored interrupt manager (VIM), ECC aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

Copyright © 2026 Texas Instruments Incorporated

Note

The Cortex-R5F processor is a Cortex-R5 processor that includes the optional floating point unit (FPU) extension. In this TRM, all references to the Cortex-R5 processor apply to the Cortex-R5F processor by default.

7.3.1.1 R5FSS Features

The R5FSS supports the following features:

- Single-core Arm Cortex-R5F
  - Core revision: r1p3
  - Armv7-R profile
  - L1 memory system
    - 32KB instruction cache
      - 4x8KB ways
      - SECDED ECC protected per 64 bits
    - 32KB data cache
      - 4x8KB ways
      - SECDED ECC protected per 32 bits
    - 64KB tightly-coupled memory (TCM)
      - SECDED ECC protected per 32 bits
      - TCM hard error cache Implemented in CPU
      - Readable/writable from system
      - TCMs initialized (to 0's) at reset
      - Split into A and B banks (with B further splitting into B0 and B1 interleaved banks)
        - 32KB TCMA (ATCM)
        - 16KB TCMB0 (B0TCM)
        - 16KB TCMB1 (B1TCM)
  - Low interrupt latency with restartable instructions
  - Non-maskable interrupt (NMI)
  - Full-precision floating point (VFPv3)
  - 16 region memory protection unit (MPU)
  - 8 breakpoints
  - 8 watchpoints
  - Dynamic branch prediction with global history buffer and 4-entry return stack
  - CoreSight debug access port (DAP)
  - CoreSight embedded trace macrocell (ETM-R5) interface
  - Performance monitoring unit (PMU)
- Interfaces
  - 64-bit VBUSM initiator pair (1 read, 1 write) for L3 memory accesses
  - 64-bit VBUSM target for TCM access
    - Also allows access to cache for debug purposes
  - 32-bit VBUSP initiator for peripheral access
  - 32-bit VBUSP target configuration port
  - 32-bit VBUSP target debug port
    - Allows access to all R5FSS internal debug logic
- Synchronous clock domain crossing on all interfaces
  - Interfaces can run at an integer multiple of the core frequency
- 32-bit to 36-bit region-based address translation (RAT) on memory access initiators
  - 4 regions
    - Base address + size
    - Must be size aligned

Copyright © 2026 Texas Instruments Incorporated

- Integrated vectored interrupt manager (VIM)
  - 256 interrupts
    - Each interrupt programmable as either IRQ or FIQ
    - Each interrupt has a programmable enable mask
    - Each interrupt has a programmable 4-bit priority
  - Priority interrupt supported
  - Vectored interrupt interface
    - Compatible with R5F VIC port
    - Programmable 32-bit vector address per interrupt
      - Address is SECDED error protected
      - Default vector addresses provided on DED
    - Software interrupt generation
- Integrated ECC aggregators
  - Support for error injection to all supported ECC memory blocks to test ECC functionality (add-on function from TI)
  - One ECC aggregator to cover all RAMs and caches
- Standard Arm CoreSight debug and trace architecture at the R5FSS level
  - Cross triggering: Supported by cross trigger interface (CTI) (per CPU) and cross trigger matrix (CTM) components
  - Processor trace: Supported by embedded trace macrocell (ETM) (per CPU) and advanced trace bus (ATB) funnel components
- Boot
  - From ROM only

See Section 7.3.2 for a functional block diagram and more details on the R5FSS.

Note

Some features may not be available. See *Module Integration* for more information.

7.3.2 R5FSS Functional Description

7.3.2.1 R5FSS Block Diagram

Figure 7-4 shows the R5FSS block diagram.

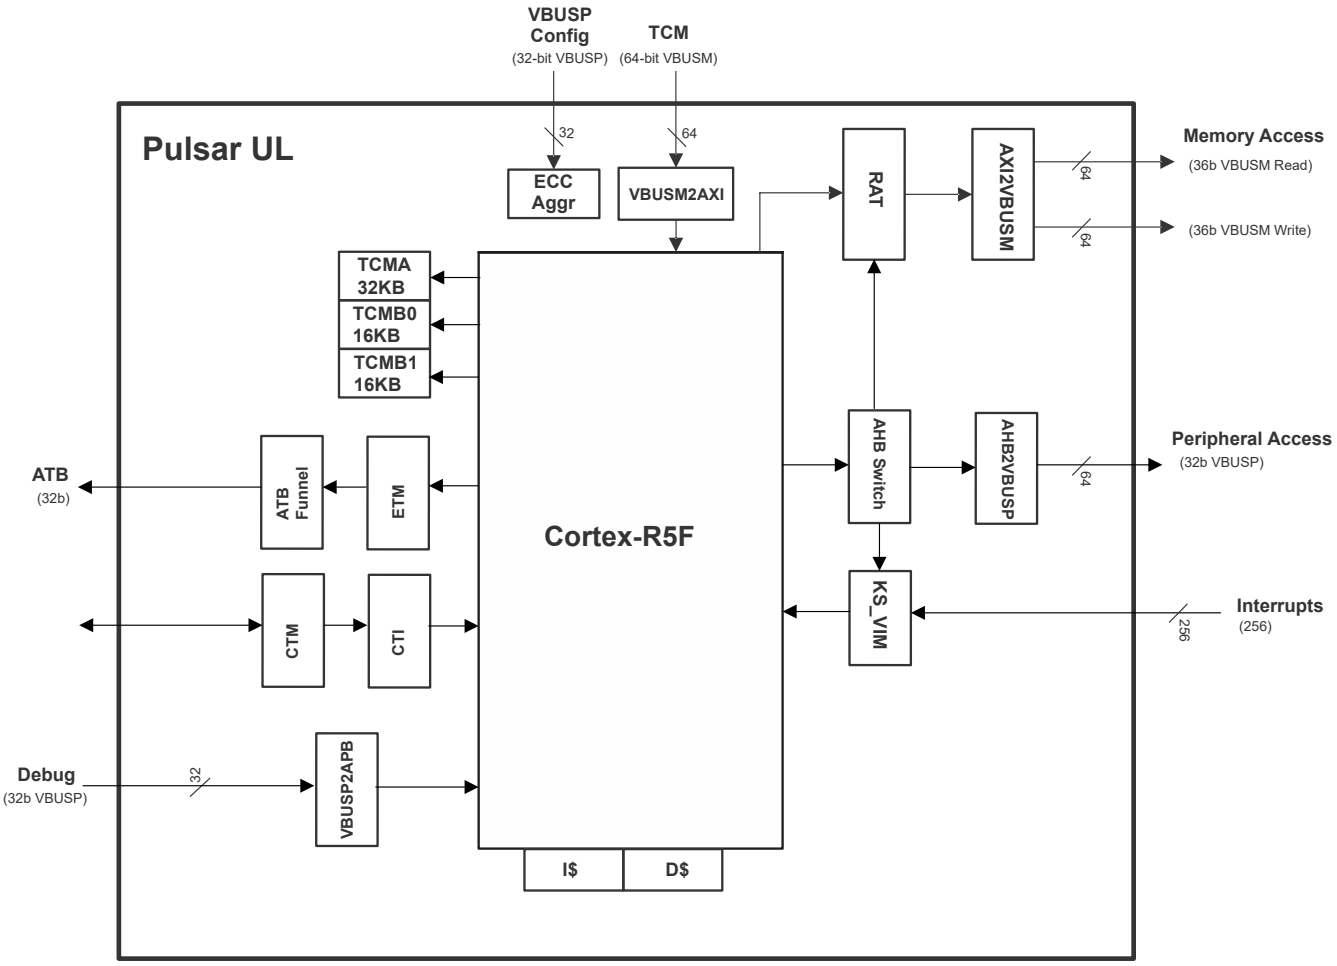

Figure 7-4. R5FSS Block Diagram

7.3.2.2 R5FSS Cortex-R5F Core

The Cortex-R5F is a processor from Arm, which is based on the Armv7-R profile.

For a brief list of features supported by the R5F processor in this device, see Section 7.3.1.1. For more detailed description of this processor, see the *Arm Cortex-R5 Technical Reference Manual*.

7.3.2.2.1 L1 Caches

The R5F has a Harvard cache architrecture, which means it has an independent L1 instruction cache (16KB) and L1 data cache (16KB). The instruction cache is protected by SECDED ECC per 64 bits. The data cache is protected by SECDED ECC per 32 bits.

7.3.2.2.2 Tightly-Coupled Memories (TCMs)

The R5F has two tightly-coupled memories (TCMs), ATCM and BTCM. The BTCM is further broken down into two interleaved banks, B0TCM and B1TCM.

TCMs are low-latency, tightly integrated memories for the R5F to use. Either TCM can be used for any combination of instruction and/or data. TCM performance is equal to performance on instructions/data that are in cache. However, TCMs have some additional advantages over cache. TCMs can be loaded with instructions

Copyright © 2026 Texas Instruments Incorporated

that do not cache well (such as ISRs) or preloaded with code by an external source, before that code is needed, to save cache miss time. TCMs are also a good place for blocks of data for intense processing. They can be loaded (or pre-loaded by an external source) before the data is needed, saving cache miss time. The data can then be directly accessed by an external source, instead of needing to do cache evicts.

As mentioned, TCMs can be accessed (either read or written) by an external source over the TCM VBUSM target interface. This allows instructions or data to be preloaded, or for data to be read out after the R5F has processed it. The VBUSM target has a lower priority to accessing TCMs than the R5F but care must be taken to keep an external source from reading or writing TCM data that the R5F is working on. This handshaking is external to any of the R5FSS hardware.

TCMs are protected by ECC per 32 bits. For this to work, ECC must be enabled before data is written in to the TCMs (either externally or from the R5F). ECC is enabled via the following R5F system control bits: ACTLR.ATCMPCEN, ACTLR.B0TCMPCEN, and ACTLR.B1TCMPCEN, respectively.

Whether or not the TCMs are enabled is controlled by the ENABLE bit in the corresponding ATCM/BTCM region register. The default (reset) value of this bit is determined by the CPUn_INITRAMA and CPUn_INITRAMB bootstraps, respectively. Both ATCM and BTCM are configured for a size of 32KB in this device. Note that the BTCM size is the total of both B0TCM and B1TCM (16KB each).

If a TCM is not enabled, then it does not appear in the R5F's memory view, but it can be accessed by an external source. If a TCM is enabled, then its place in the R5F memory map is determined by a combination of bootstrap signal and system register. If the CPUn_LOCZRAMA bootstrap signal is high, then the initial base address of ATCM is 0x0000_0000 and the initial address of BTCM is 20'h41010. If the CPUn_LOCZRAMA bootstrap signal is low, then the initial base address of BTCM is 0x0000_0000 and the initial base address of ATCM is 20'h41010.

Note

This base address of 0x41010 for ATCM/BTCM based on the CPUn_LOCZRAMA bootstrap only affects the R5F's memory view. The SoC will see the ATCM/BTCM based on the TCM target interface regions, as defined in Section 7.3.2.3.2. The base address of either TCM may be overwritten via the ATCM or BTCM region register. Care must be taken not to move the base address of a TCM when it may be being accessed.

It is possible to preload a TCM with instructions and boot from it. See Section 7.3.2.11 for details on TCM booting.

7.3.2.2.3 R5FSS Special Signals

Table 7-11 lists some R5FSS features associated with special signals.

Table 7-11. R5FSS Special Features

Feature	Comment
Cluster affinity group ID	R5F Cluster 0 (ID = 0x0)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
CPUn execution halt when coming out of reset (CPUn_HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPUn exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPUn VIM base address	0x2FFF_0000
CPUn RAT base address	0x2FFE_0000
CPUn RAT accesses ID	0x4 (CPU0)
CPUn ATCM enable at reset (CPUn_INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state

Copyright © 2026 Texas Instruments Incorporated

Table 7-11. R5FSS Special Features (continued)

Feature	Comment
CPUn BTCM enable at reset (CPUn_INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPUn A/BTCM reset base address indicator (CPUn_LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPUn non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPUn VBUSM peripheral port enabled at reset	Enabled
CPUn VBUSP peripheral port enable at reset	Enabled
CPUn VBUSP peripheral port base address	Mapped to 0x0_2000_0000 for low latency MAIN peripherals
CPUn VBUSP peripheral port size	64MB for MAIN peripherals (0x0_2000_0000 to 0x0_2FFF_FFFF)
CPUn VBUSM normal peripheral port base address	Not used
CPUn VBUSM normal peripheral port size	Not used
CPUn VBUSM virtual peripheral port base address	Not used
CPUn VBUSM virtual peripheral port size	Not used
CPUn clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPUn WFI state	Status logged into MAIN_SEC_MMR register bit
CPUn WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

7.3.2.3 R5FSS Interfaces

7.3.2.3.1 Initiator Interfaces

The R5FSS has several initiator interfaces:

- 64-bit VBUSM initiator pair (1 read - "RMST", 1 write - "WMST") for L3 memory accesses; this is the main memory interface
  - Includes region-based address translation (RAT)
- 32-bit VBUSP initiator "PMST" for peripheral access
  - Includes logic that provides the R5F CPU with a private access to VIM and RAT
  - Enabled at reset

7.3.2.3.2 Target Interfaces

The R5FSS has several target interfaces that define its internal memory space:

- 32-bit VBUSP configuration target
  - Region [0]: ECC aggregator block
- 64-bit TCM target
  - Region [0]: ATCM
  - Region [1]: BTCM
  - Region [2]: Instruction cache RAMs
  - Region [3]: Data cache RAMs
- 32-bit VBUSP debug target
  - Provides access to all R5FSS internal debug logic

Regions [0] and [1] of the TCM target interface provide direct access to the TCM RAMs. Access to the RAMs is arbitrated with access from the R5F's L1 memory system. Excessive access while the R5F is also attempting access will degrade performance.

Regions [2] and [3] of the TCM target interface provide access to the cache RAMs for testing purposes. Access to the cache RAMs can only be done while the caches are disabled and should only be done for test purposes.

Copyright © 2026 Texas Instruments Incorporated

In addition to the target interfaces, there are peripherals (RAT and VIM) that are only accessible by the R5F. The R5F has an access to these modules via the VBUSP peripheral interface.

7.3.2.4 R5FSS Power, Clocking and Reset

7.3.2.4.1 R5FSS Power

The following R5FSS power considerations should be noted:

- R5FSS has a single power domain for all its internal logic

For more details on R5FSS power management, including power-up and power-down sequences, see *Power*.

7.3.2.4.2 R5FSS Clocking

The R5FSS has four clock inputs:

- CPU0_CLK: This is the clock for CPU0 logic
- CPU0_ICLK: This is the clock for CPU0 interfaces

CPU0_CLK is the clock for all of the internal CPU logic, while CPU0_ICLK is the clock for all of the interfaces for their associated CPU (for example: VBUSM and VBUSP bridges, exception generation, debug and trace logic).

The interface clock is an integer ratio of the CPU clock. The exact ratio for this device is 1:1.

7.3.2.4.3 R5FSS Reset

The R5FSS has two reset inputs:

- CPU0_RST: This is the reset for the non-debug logic of CPU0
- CPU0_DBG_RST: This resets the CPU0 debug logic, excluding the APB interface

In addition to the reset signals, there is one halt signal:

- CPU0_HALT

These halt signals keep the CPUs from fetching instructions when they come out of reset. The main use is to have the CPUs halted until the TCMs are loaded (when booting from TCM), though halt could be used for any other purpose.

7.3.2.5 R5FSS Vectored Interrupt Manager (VIM)

7.3.2.5.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU. It can be used in either split or single-core configuration.

The VIM module supports the following features:

- 256 interrupt inputs for the R5F core
- Each interrupt has its own 4-bit programmable priority
  - Defined via the R5FSS_VIM_PRI_INT_j register
  - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
  - Interrupt enable is done via the R5FSS_VIM_INTR_EN_SET_j register
  - Interrupt disable is done via the R5FSS_VIM_INTR_EN_CLR_j register
- Each interrupt can be programmed as either an IRQ or FIQ
  - Defined via the R5FSS_VIM_INTMAP_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
  - Defined via the R5FSS_VIM_VEC_INT_j register
  - Protected with SECDED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
  - Compatible with R5F VIC port
- Default vector provided when a double-bit error is detected

Copyright © 2026 Texas Instruments Incorporated

- Software interrupt generation

7.3.2.5.2 VIM Interrupt Inputs

The VIM supports 256 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the R5F core can be found in *Interrupt Sources*.

7.3.2.5.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- *CoreN_IRQn*: This is a normal interrupt for core *N* (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the R5FSS_VIM_INTMAP_j register) and is enabled (via the R5FSS_VIM_INTR_EN_SET_j register), then it will cause an IRQ to assert
- *CoreN_FIQn*: This is a fast (or non-maskable) interrupt for core *N* (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

7.3.2.5.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (R5FSS_VIM_VEC_INT_j). Hence, the interrupt vector table is organized in 256 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

Note

The lower two bits of the 32-bit interrupt vector are always 0s.

Figure 7-5 shows the VIM RAM interrupt vector map.

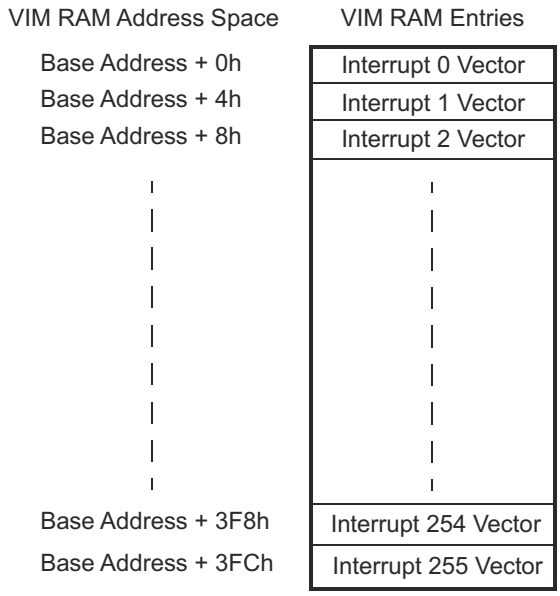

Figure 7-5. VIM RAM Interrupt Vector Map

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. See Table 7-14 for the VIM RAM ID in the ECC aggregator map.

Copyright © 2026 Texas Instruments Incorporated

7.3.2.5.5 VIM Interrupt Prioritization

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the R5FSS_VIM_FIQVEC register; IRQ: reading the R5FSS_VIM_IRQVEC register, or the *coreN_IRQACK* going high), then the interrupt is loaded into the corresponding active register (R5FSS_VIM_ACTFIQ / R5FSS_VIM_ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to the R5FSS_VIM_FIQVEC register, or R5FSS_VIM_IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. If the CPU switches this interrupt to active (by reading the R5FSS_VIM_FIQVEC / R5FSS_VIM_IRQVEC register), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by reading the R5FSS_VIM_FIQVEC / R5FSS_VIM_IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the R5FSS_VIM_ACTFIQ / R5FSS_VIM_ACTIRQ register, so that software may continue where it left off.

7.3.2.5.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the R5FSS_VIM_DEDVEC register is used to provide the default vector for the *coreN_IRQADDRV* signal, the R5FSS_VIM_IRQVEC register, and the R5FSS_VIM_FIQVEC register. The R5FSS_VIM_DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
   a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device
4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt . This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by the R5FSS ECC aggregator.

7.3.2.5.7 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

7.3.2.5.8 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in Section 7.3.2.5.8.1, but the procedures in Section 7.3.2.5.8.2 or Section 7.3.2.5.8.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

For FIQs, it is recommended to use the procedure in Section 7.3.2.5.8.4, but the procedure in Section 7.3.2.5.8.5 may be used as an alternative.

Copyright © 2026 Texas Instruments Incorporated

Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

7.3.2.5.8.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
   a. CPU asserts *coreN_IRQACK* high
   b. VIM asserts *coreN_IRQADDRV* to indicate that the *coreN_IRQADDR* bus is stable with the correct vector address
   c. CPU reads *coreN_IRQADDR*, jumps to that address, and de-asserts *coreN_IRQACK* low
   d. VIM de-asserts *coreN_IRQn* and *coreN_IRQADDRV*, VIM masks (discards) all IRQs with the same or lower priority
   e. VIM loads the value from the R5FSS_VIM_PRIIRQ[9:0] NUM bit field (which corresponds to the vector address) into the R5FSS_VIM_ACTIRQ[9:0] NUM bit field, which causes the R5FSS_VIM_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS_VIM_ACTIRQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS_VIM_INTTYPE_j register to determine type)
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_IRQSTS_j register, or R5FSS_VIM_STS_j register
      ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_IRQSTS_j register, or R5FSS_VIM_STS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS_VIM_IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTIRQ[31] VALID bit

7.3.2.5.8.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the R5FSS_VIM_IRQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN_IRQn* will re-assert, allowing priority interruption of an interrupt
   b. Reading this register will cause the value from the R5FSS_VIM_PRIIRQ[9:0] NUM bit field to be loaded into the R5FSS_VIM_ACTIRQ[9:0] NUM bit field, and the R5FSS_VIM_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse

Copyright © 2026 Texas Instruments Incorporated

i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
ii. Clear the interrupt at the source

b. Level
i. Clear the interrupt at the source
ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register

4. Write any value to the R5FSS_VIM_IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTIRQ[31] VALID bit

7.3.2.5.8.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the R5FSS_VIM_IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS_VIM_IRQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the R5FSS_VIM_PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
   b. Optionally read the R5FSS_VIM_IRQGSTS register to determine which groups have IRQs pending, then read the R5FSS_VIM_IRQSTS_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
      ii. Clear the interrupt at the source.
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register

7.3.2.5.8.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the R5FSS_VIM_FIQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN_FIQn* will re-assert, allowing priority interruption of an interrupt.
   b. Reading this register will cause the value from the R5FSS_VIM_PRIFIQ[9:0] NUM bit field to be loaded into the R5FSS_VIM_PRIFIQ[9:0] NUM bit field, and the R5FSS_VIM_ACTFIQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS_VIM_ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS_VIM_INTTYPE_j register to determine type)
   a. Pulse

Copyright © 2026 Texas Instruments Incorporated

i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register
ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt

b. Level
i. Clear the interrupt at the source
ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt

4. Write any value to the R5FSS_VIM_FIQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTFIQ[31] VALID bit

7.3.2.5.8.5 Servicing FIQ (Alternative)

If a user does not want to use the R5FSS_VIM_FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS_VIM_FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the R5FSS_VIM_FIQVEC register to determine which interrupt is the highest priority FIQ currently asserted, OR
   b. Optionally read the R5FSS_VIM_FIQGSTS register to determine which groups have IRQs pending, then read the R5FSS_VIM_FIQSTS_j register and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register
      ii. Clear the interrupt at the source.
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register.

7.3.2.6 R5FSS Region Address Translation (RAT)

The R5F is a 32-bit processor, which means it can only access 4GB of directly addressable memory. The R5FSS includes a region-based address translation (RAT) unit per core, which allows the R5F to access higher address ranges. The R5FSS RAT module translates a 32-bit input address into a 36-bit output address. It supports 4 regions. For more details on RAT functionality, refer to *Region-based Address Translation (RAT) Module*.

7.3.2.6.1 WKUP R5FSS Usage

R5 is a micro controller with 32b address, which is only able to access up to 4GB address space. However, Sitara™ SoC supports 36b address and majority of the memory region beyond lower 4GB are implemented. Region based address translation block, called RAT, is introduced to allow R5 core to access full 36b SoC memory map.

Each R5 core has its own RAT block, and only R5 core itself is able to program the RAT.

Copyright © 2026 Texas Instruments Incorporated

Figure 7-6 shows the main R5's default 32b memory map view when main R5 is out of reset.

The full RAT functionality is described in Section 7.3.2.6.2, *RAT Function*.

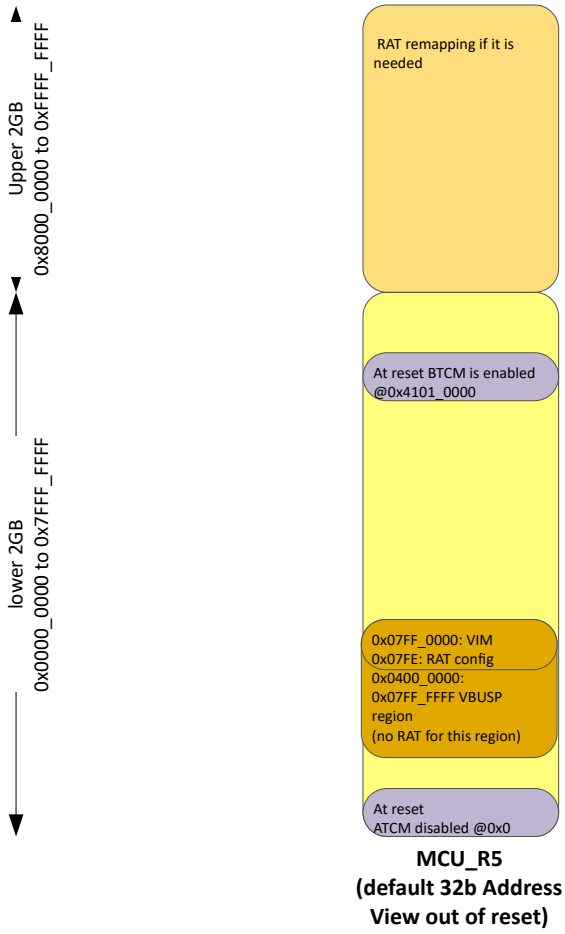

Figure 7-6. R5 Core Default Memory Map View

Copyright © 2026 Texas Instruments Incorporated

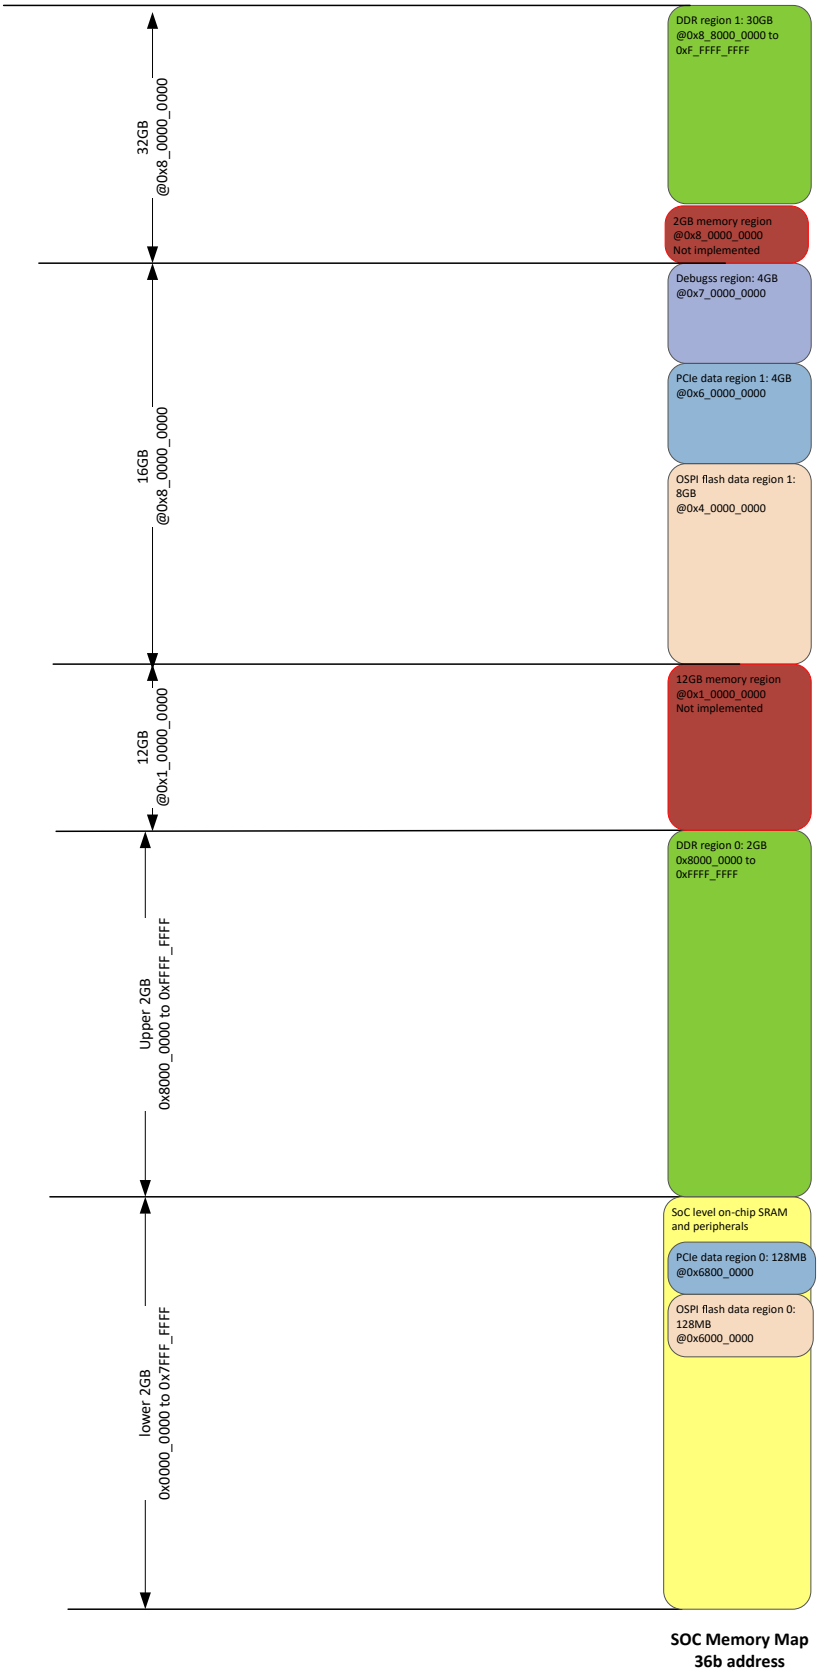

Figure 7-7. Typical Sitara SoC Memory Map View

Copyright © 2026 Texas Instruments Incorporated

RAT block enables R5 core to have full access on the SoC memory map including the memory region at and above 0x1_0000_0000.

Figure 7-8 shows how R5 access various end points, including its own ATCM, BTCM, VIM and SoC memory and peripherals. R5's ATCM is by default at address 0x0, and its BTCM is at address 0x4101_0000. R5 uses address 0x07FF_0000 to access its VIM and 0x07FE_0000 to access the RAT configuration region and all the other transactions between address range 0x0400_0000 to 0x07FF_FFFF are sent to the 32b peripheral interface to access the peripherals in SoC. The transactions with the rest of address are sent to RAT block, which could go through address remapping function from original R5's 32b address to 36b SoC address.

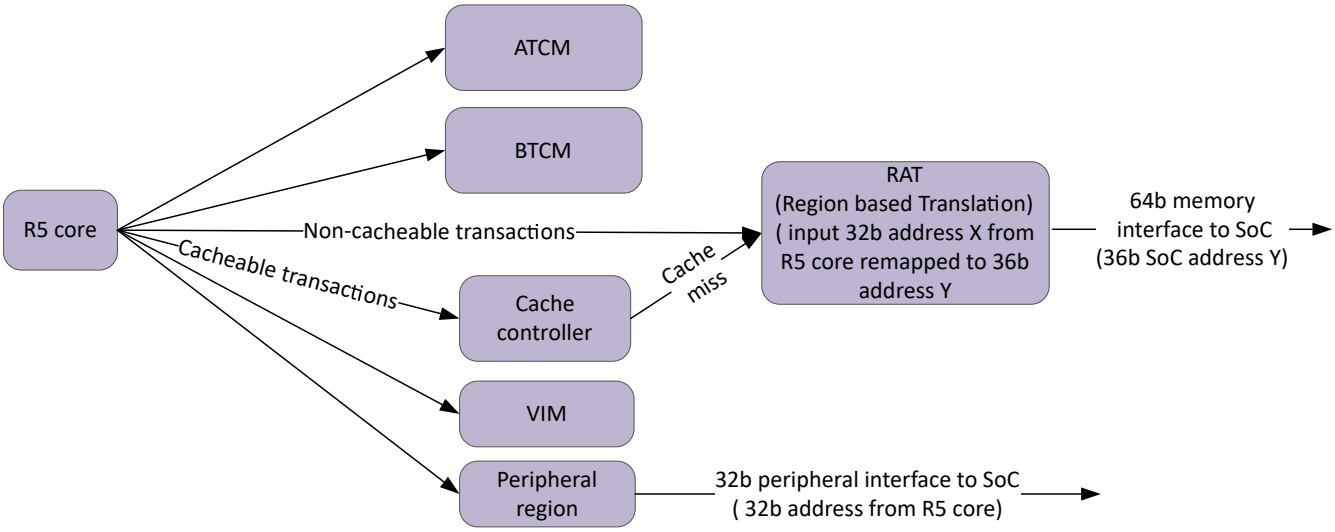

Figure 7-8. R5 Internal Address Decoding

7.3.2.6.2 RAT Function

RAT block is responsible to do a region based address translation. For each region, user can define the starting address and size of the region and remapping the transactions to use a new address range.

The starting address and region size need to be aligned. For example, if the region size is 16KB, the starting address for that region needs to be 16KB aligned. And region size should be minimum 4KB or larger to avoid transactions cross the region boundaries.

Each RAT block supports multiple programmable regions. And it is important that those regions are not overlapping with each other.

RAT block is by default disabled, which means RAT block does not do address remapping. The 32b address coming from R5 core is directly sent out to the SoC level. The user can program each RAT remapping region individually. For the transactions does not hit any remapping region, RAT block just simply forwards the transactions to the SoC level with its original address.

7.3.2.6.3 How to use RAT Block in R5

Table 7-12 shows the default R5 memory map view. Without enabling RAT function, all the regions beyond 4GB address space will not be accessible by R5.

Sitara™ SoC memory map is constructed the way to allow R5 and high level application processor such as A53 have similar memory map as possible. This methodology enables that R5 and ARM A53 core have a common memory map for all the SoC level memories and SoC level peripherals except a few exceptions:

- DDR's data space beyond 32b address, basically upper DDR data space beyond 2GB
- PCIe data space beyond 32b address
- OSPI data space beyond 32b address
- Debug configuration region

Copyright © 2026 Texas Instruments Incorporated

Table 7-12. R5 Memory map by Default

	R5 Memory Map(32b)	SoC Memory Map (36b)
SoC Level peripheral and on-chip SRAM	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF
2GB DDR region	Same as SoC memory map: 0x8000_0000 to 0xFFFF_FFFF	0x80000_0000 to 0xFFFF_FFFF
Additional DDR region	Not accessible	0x8_8000_0000 (30GB)
Additional 8GB OSP Space	Not accessible	0x4_0000_0000 (4GB) 0x5_0000_0000 (4GB)
Additional PCIe data space	Not accessible	0x6_000_0000
Debug configuration region	Not accessible	0x7_0000_0000

Even though all the transactions other than going to ATCM/BTCM and transactions between address range 0x0400_0000 to 0x07FF_FFFF could use RAT block to remap to different address, it is recommended that only use RAT block to remap the R5 transactions with address between 0x8000_0000 to 0xFFFF_FFFF.

- Any transactions from R5 with address between 0x0 to 0x7FFF_FFFF are sent out to SoC directly (unless it is targeted to its internal end points such as A/B TCM, its VIM and RAT configuration)
- Only enable RAT to remap the transactions with address between 0x8000_0000 to 0xFFFF_FFFF if R5 needs to access the following address space:
  - PCIe data space at address 0x6_0000_0000
  - OSPI data space address 0x4_0000_0000 and 0x5_0000_0000
  - Debug configuration region at address 0x7_0000_0000
  - DDR data space at address 0x8_8000_0000

Copyright © 2026 Texas Instruments Incorporated

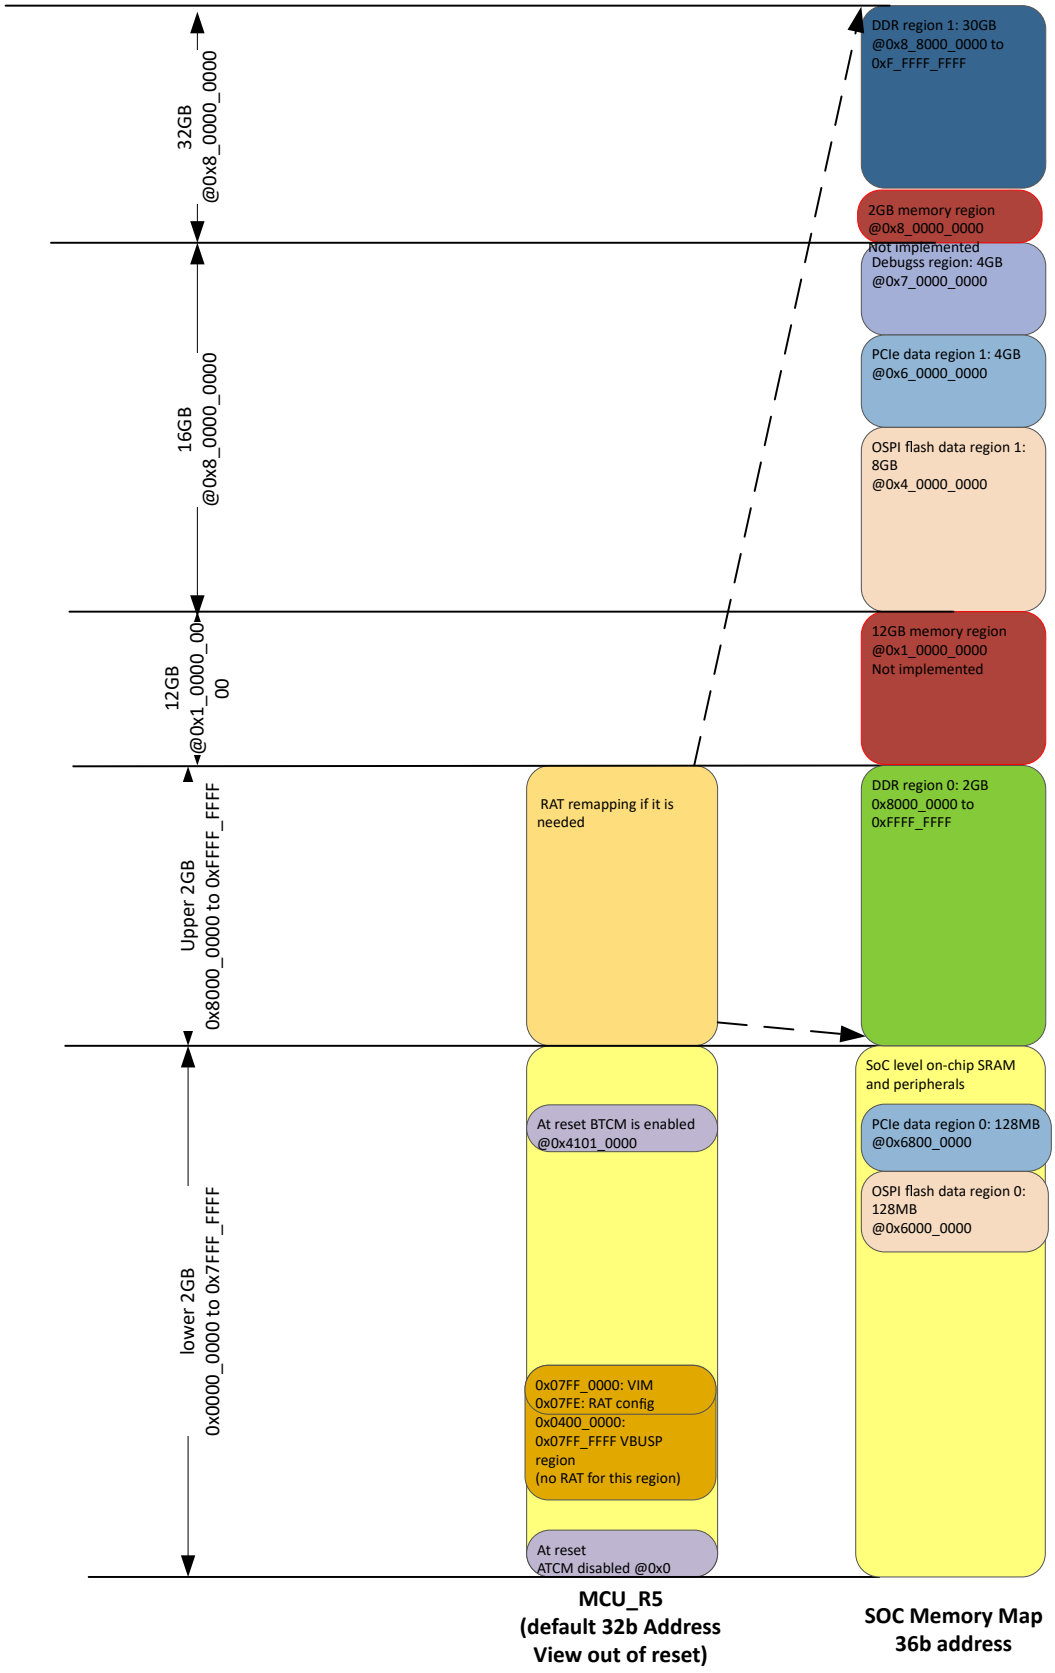

Figure 7-9. Example of Using RAT to Access Full 36b SoC Memory Map

Copyright © 2026 Texas Instruments Incorporated

7.3.2.6.4 Example of Using RAT to Access Full 36b SoC Memory Map

This section shows an example on how to utilize RAT block to allow R5 to access 36 SoC Memory Map. The RAT block inside R5 has up to 8 address remapping regions.

Assuming R5 needs to access the following region:

- All the SoC level on-chip SRAM
- All the SoC level peripherals
- Access 512MB OSPI region at address 0x4_0000_0000
- Access 1GB DDR region at address 0x9_0000_0000
- Access 512MB DDR region at address 0x8000_0000

First of all, we need to construct 32b R5 memory map as following and how those memory spaces are mapped to SoC level, shown in Table 7-13. Users can define where the OSPI and DDR data space placed inside R5's memory map and how they should be mapped to SoC level address map. Table 7-13 just shows one of the many possible ways to construct the memory map.

Table 7-13. Example of R5 Address Mapping

	R5 Memory Map(32b)	SoC Memory Map (36b)	RAT Remapping
SoC Level peripheral and on-chip SRAM (This is guaranteed by SoC Hardware design. No user configuration is needed)	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF	Not RAT Remapping
512MB OSPI data region (user defined)	0x8000_0000 to 0x9FFF_FFFF	0x4_0000_0000 to 0x4_1FFF_FFFF	Using RAT remapping region 0
512MB DDR space (user defined)	0xA000_0000 to 0xBFFF_FFFF	0x8000_0000 to 0x9FFF_FFFF	Using RAT remapping region 1
Additional 1GB DDR Space (user defined)	0xC000_0000 to 0xFFFF_FFFF	0x9_0000_0000 to 0x9_3FFF_FFFF	Using RAT remapping region 2

In this example, only three RAT regions are needed:

- Region 0 is used to remap R5's address between 0x8000_0000 to 0x9FFF_FFFF to SoC level address 0x4_0000_0000 to 0x4_1FFF_FFFF
- Region 1 is used to remap R5's address between 0xA000_0000 to 0xBFFF_FFFF to 0x8000_0000 to 0x9FFF_FFFF
- Region 2 is used to remap R5's address 0xc000_0000 to 0xFFFF_FFFF to 0x9_0000_0000 to 0x9_3FFF_FFFF.

In order achieving those mappings, those are the setting of the RAT configuration registers:

	Region 0	Region 1	Region 2	Other regions
Region control register	Enabled, size set to 512MB	Enabled, size set to 512MB	Enabled, size set to 1GB	disabled
Region base(32b)	0x8000_0000	0xA000_0000	0xc000_0000	Don't care
Region translated lower address(32b)	0x0000_0000	0x8000_0000	0x0000_0000	Don't care
Region translated upper address	0x4	0x0	0x9	Don't care

Figure 7-10 shows how RAT is remapping the address between R5's 32b address to 36b SoC address.

7.3.2.7 R5FSS ECC Support

The R5F provides native ECC and parity support on all related memories, generating and checking the redundancy automatically. The methods for checking and reporting errors are available in the *Arm Cortex-R5 Technical Reference Manual*.

The R5FSS adds the capability of testing this logic by allowing errors (single and double bit) to be injected into memories (for testing purposes) via an ECC aggregator (per core). Note that because the R5FSS ECC aggregator is only used in error-injection mode, it only supports a subset of the generic ECC aggregator functionality in the device.

For a detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of the R5FSS aggregators, see R5FSS_CPU0_ECC_AGGR_CFG_REGS Registers and R5FSS_CPU1_ECC_AGGR_CFG_REGS Registers, respectively.

Table 7-14 provides the RAM ID. This is needed for bit field [10-0] ECC_VECTOR in the corresponding R5FSS_CPU0_VECTOR register (part of the ECC aggregator register space).

Table 7-14. RAM ID Map for ECC Aggregator (Per Core)

RAM ID	Memory Name
0	CPU0 ITAG RAM0
1	CPU0 ITAG RAM1
2	CPU0 ITAG RAM2
3	CPU0 ITAG RAM3
4	CPU0 IDATA BANK0
5	CPU0 IDATA BANK1
6	CPU0 IDATA BANK2
7	CPU0 IDATA BANK3
8	CPU0 DTAG RAM0
9	CPU0 DTAG RAM1
10	CPU0 DTAG RAM2
11	CPU0 DTAG RAM3
12	CPU0 DDIRTY RAM
13	CPU0 DDATA RAM0

7.3.2.8 R5FSS Memory View

The memory view of the R5F (that is, the memory map as seen by each R5F) is a function of several things:

- Exception vector bootstrap: The R5F exception table (including boot vector) is always 32 bytes at address 0x00000000 as seen by the R5F. If not booting from a TCM, then boot is done over the main memory interface. The exception vector bootstrap is under software control, which allows these 32 bytes at address 0x00000000 to be remapped somewhere else in the SoC memory map.
- TCM locations: TCMs can be enabled or disabled and located at different places in the memory map, depending on bootstrap configuration. For more details, see Section 7.3.2.2.2.
- Peripheral interface locations: The RF5 natively supports three interfaces for peripheral access. Each can be enabled/disabled and located based on bootstrap configuration. Note that the VBUSP peripheral interface must be enabled in order to use RAT and VIM.
- RAT base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- VIM base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- RAT programming: The RAT can take regions of memory accessible by the main memory interface and map them to different addresses.

The combination of the above determines what the R5F sees where in the memory map, and over what interface different transactions come out. Every transaction that does not directly address a TCM or a peripheral interface comes over the main memory interface. Transactions on the main memory interface can be further remapped with the RAT.

See *Memory Map*, for the complete R5F memory view for this device.

7.3.2.9 R5FSS Interrupts

All interrupts that are generated by the R5FSS are summarized in *Module Integration*, along with their mapping. They can be divided into the following groups:

- R5F CPU internal interrupts: These are described in *Arm Cortex-R5 Technical Reference Manual*.
- ECC aggregator interrupts: These are described in the *ECC Aggregator* chapter.
- RAT exception interrupt: This is described in Section 7.3.2.6.

7.3.2.10 R5FSS Debug and Trace

The R5FSS supports standard Arm CoreSight debug and trace architecture. For more details, see the *On-chip Debug* chapter.

7.3.2.11 R5FSS Boot Options

There are two methods of booting the R5F, or rather, two methods of placing the exception vectors (of which the boot vector is one).

The first method is to have the exception vectors external to the R5F. The user can place the exception vectors at the address indicated by the exception vector bootstrap and then program the boot vector there. When the processor exits reset, it will fetch the boot vector from this location.

The second method is to boot from a TCM. To do this, software should take the following steps:

1. Assert the correct bootstraps
   a. To boot from ATCM, set CPUn_INITRAMA (or CPUn_INITRAMB to boot from BTCM)
   b. Assert CPUn_LOCZRAMA properly for the desired TCM
2. Assert CPUn_HALT
3. Release the CPU from reset
4. Load the desired code into the TCM via the TCM target port
   a. Exception vectors should be located at address 0x00000000 of the TCM
5. De-assert CPUn_HALT

7.3.2.12 R5FSS Core Memory ECC Events

The R5F core generates several events as part of event bus that can be monitored by the PMU for debugging. The memory ECC related events from the event bus are exported to ESM for monitoring.

There are two ECC interrupts to the ESM that aggregate different categories of ECC events – CPU single error, CPU multi error. Each ECC event has a 2-bit event bus counter associated with it. Everytime an event occurs, the counter is incremented by 1 till it reaches the max value of 3. The interrupt is asserted if the bus counter of any event associated with the interrupt is non-zero.

Each event bus counter has a MMR decrement control to decrement the counter by 1. So, for example, if a counter value is 2, the MMR to decrement the counter would need to be written 2 times to decrement the counter to 0. The reason decrement control has been added instead of clear control is if a new error occurs between the time the status register is read and the clear MMR is written, the new error would be lost. Write-to-decrement ensures that this does not happen.

When all event bus counters of an associated interrupt are zero, the interrupt is cleared. It takes three clock cycles for the event bus counter to be decremented once the write to the decrement control MMR presents itself at the R5FSS boundary.

Since each of the four ECC interrupts have single bit control to set the interrupt but multiple bits for clearing it, note that once an interrupt is set using the R5FSS_EVNT_BUS_ESM_SET register, it can be cleared by setting all the bits of the R5FSS_EVNT_BUS_ESM_CLR register that correspond to that particular interrupt. For example, if bit [0] of the R5FSS_EVNT_BUS_ESM_SET register is set, it can be cleared by setting bits [7-0] of the R5FSS_EVNT_BUS_ESM_CLR register to clear the interrupt.

The R5F core event bus only signals event when it is enabled. Non-invasive or invasive debug mode needs to be enabled to enable the PMU counters.

The export of the events to the event bus can be enabled by setting the X bit in the Performance Monitor Control Register of the R5F core. For more details, refer to Arm R5 TRM.

Table 7-15. R5F Event Bus Single-Bit Error Events

Event Bus Bit #	Description	Associated Status Register

7.3.3 Vectored Interrupt Manager (VIM)

This section describes the VIM module in the device.

7.3.3.1 VIM Overview

The Vectored Interrupt Manager (VIM) aggregates interrupts to a CPU. It is intended for use with a Cortex R5 from ARM. The VIM has up to 1024 interrupt inputs, which may be either level or pulse. Each interrupt has a programmable priority (0-highestthrough 15-lowest). Each interrupt may also be mapped as an IRQ or FIQ (FIQ is also often denoted as Non-Maskable Interrupt, or NMI).

7.3.3.1.1 VIM Features

- 32-1024 Interrupt inputs
  - Configurable by groups of 32
- Each interrupt has its own 4-bit programmable priority
  - Supports Priority interruption of interrupts
- Each interrupt has its own enable mask
- Each interrupt can be programmed as either an IRQ or FIQ
- Each interrupt has its own programmable 32-bit Vector address associated with it
  - Protected with SECDED
- One IRQn and FIQn output
- Vectored Interrupt Interface
  - Compatible with ARM Cortex R5 VIC Port
- Default Vector provided when a Double-Bit error is detected
- Provides clock phase inputs so VIM can run at CPU clock while interface runs at a different, synchronous clock

7.3.3.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

Note

Some features may not be available. See *Module Integration* for more information.

7.3.3.2 VIM Functional Description

7.3.3.2.1 Block Diagram

Figure 7-11 shows the Vectored Interrupt Manager block diagram.

Copyright © 2026 Texas Instruments Incorporated

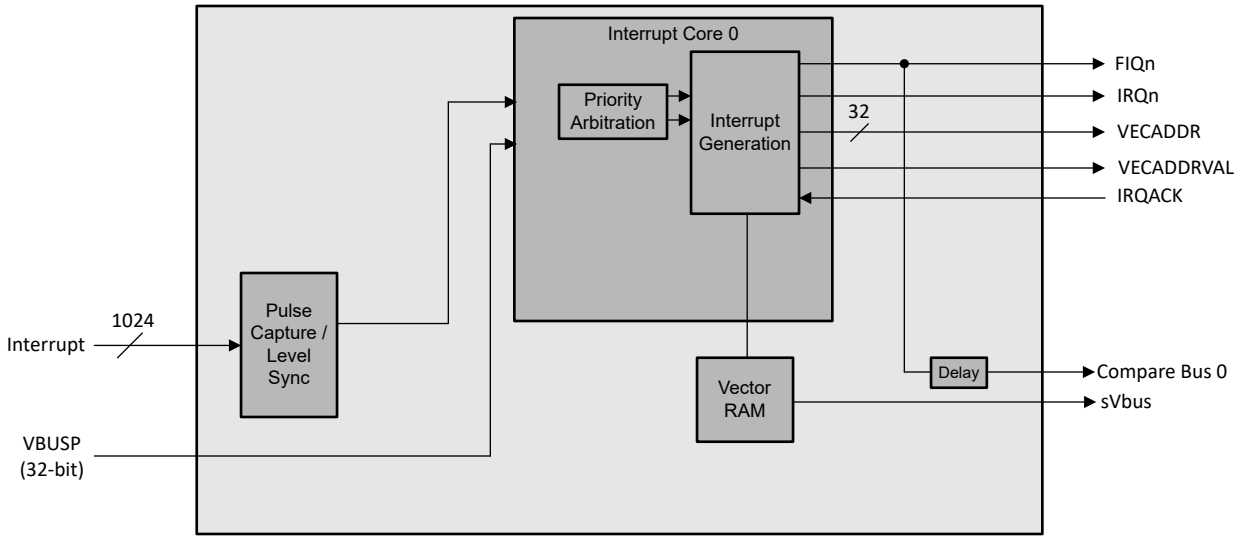

Figure 7-11. VIM Block Diagram

7.3.3.2.2 Interrupt Inputs

The VIM can have up to 1024 interrupt inputs, build-time configurable by multiples of 32 (*num_interrupts* parameter). Each interrupt can be either a level or a pulse (both active high).

Level interrupts are synchronized to the VIM clock. This synchronized value is captured in to a flop.

Pulse interrupts use rising edge detection. Each input has its own edge detection circuit. It is recommended that if pulses are pipelined between the source and the VIM, that the pipe stage replicates the pipe flop and ORs the output in order to protect against transient errors in the pipeline flop. Once an edge has been detected, the raw status is set.

There is no minimum pulse width, as true edge detection is used. The input signal should, however, be glitch free.

7.3.3.2.3 Interrupt Outputs

The VIM has two interrupt outputs, core*N*_IRQn and core*N*_FIQn (active low levels). Each interrupt input for core *N* can be programmed to influence either the core*N*_IRQn or core*N*_FIQn output via the Group *M* Interrupt Map Register (Base Address + 0x200 + *N**0x20 + 0x18).

7.3.3.2.4 Priority Interrupt / Nested Interrupts

Each interrupt has a priority number assigned to it (set using the 4.1.20 Interrupt *Q* Priority Register (Base Address + 0x1000 + *Q**0x4) register). Legal values are 0 to 15 where 0 is the highest priority and 15 is the lowest priority. The highest priority interrupt is the pending interrupt with the smallest priority number. If two pending interrupts have the same priority, the interrupt lowest numerically (0 through maximum number of interrupts) is prioritized. IRQs and FIQs are prioritized separately.

The VIM supports the interrupt of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate, but both use the same mechanism. When an interrupt goes from pending to active (FIQ: reading the FIQ Vector Address (Base Address + 0x1C), IRQ: reading the IRQ Vector Address (Base Address + 0x18) or the core*N*_IRQACK going high), then the interrupt is loaded into the corresponding Active Register, and all interrupts of an equal or lesser priority are masked off (see note below). If, before this interrupt is cleared (writing the FIQ Vector Address (Base Address + 0x1C) or IRQ Vector Address (Base Address + 0x18)) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. The CPU may or may not service the higher priority interrupt. If the CPU switches this interrupt to active, by reading the corresponding Vector Address Register (or core*N*_IRQACK going high for an IRQ) , then the currently active interrupt will be pushed on to a stack. When an interrupt is cleared by writing the Vector Address Register, if there are any interrupts on the stack, the first entry is popped off and put back into the Active

Copyright © 2026 Texas Instruments Incorporated

Register, so that software may continue where it left off. Note that the IRQVEC/FIQVEC address registers are *not* repopulated with the old vector as it's assumed that the ISR is picking back up where it left off. Only the interrupt number and priority are restored to the ACTIRQ/ACTFIQ registers. If software needs the vector again, it will have to read it by using the interrupt number.

Note

"Masked off" means that they are masked off from priority arbitration to interrupt the currently active interrupt, it does NOT mean that the status bits in the regsiters are masked off. That is, this priority masking has NO EFFECT on whether the status bits are visible in the masked registers such as the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04).

7.3.3.2.5 VIC Port

The VIM is designed to work with the VIC interface of an ARM Cortex R5.

7.3.3.2.6 Latency

There are several factors that go in to the speed of processing an interrupt: the interrupt controller, the processor, and the system latency.

The VIM behaves deterministically (except for synchronizer delay). Table 7-17 shows the latency of the VIM.

Table 7-17. VIM Latency

Step	Cycles	Note
Edge Detection	2-3	Synchronizing to VIM Clock
Interrupt Capture	1	
Prioritization and Vector Read	1	IRQ Could be stalled here if an FIQ is reading the Vector RAM
		IRQ/FIQ output asserted

The next factor is the processor itself

Table 7-18. Processor Interrupt Latency

Step	Cycles(1)	Note
Take Exception		
Store State		Stack system registers etc
Read Vector	1	Through MMR or VIC interface (for IRQ. VIC interface will be faster)
Jump to Vector		

(1) These steps are dependent on the processor. See R5 spec for details.

The final factor is system latency to access the actually instructions for the ISR. This will be dependent on where the instructions are (cache, TCM, system memory etc) and dependent on the system latency to reach those memories (1 cycle for cache/TCM, System dependent for external memory)

7.3.3.2.7 Safety

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the DED Vector Address (Base Address + 0x30) is used instead for the core*N*_IRQADDRV, IRQ Vector Address (Base Address + 0x18), and FIQ Vector Address (Base Address + 0x1C). The DED Vector Address should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling. Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
   a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device

Copyright © 2026 Texas Instruments Incorporated

4. Sit in a loop (or WFI) while something external (say the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

An interrupt that has an uncorrectable vector error and thus uses the DED Vector, will still have the priority of the original interrupt (that is for masking purposes). This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by an external ECC aggregator through sVbus ports.

7.3.3.2.8 IDLE

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface because it does not have a clock IPG. To clock stop the sub-system that includes the VIM, disable (mask) all interrupts and wait for the IDLE signal to assert.

7.3.3.3 Interrupt Conditions

7.3.3.3.1 CPU Interrupts

See Table 7-19 for the interrupts generated by the module.

Table 7-19. Interrupts

Interrupt	Description
core0_IRQn	IRQ Interrupt (Active Low)
core0_FIQn	FIQ Interrupt (Active Low)

7.3.3.3.2 Interrupt Description

7.3.3.3.2.1 coreN_IRQn

This is a normal interrupt, active low level, for Core N. It can be serviced via the VIC interface or through the MMR interface.

7.3.3.3.2.2 coreN_FIQn

This is a fast (or non-maskable) interrupt, active low level, for Core N. FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface.

7.3.3.3.3 Interrupt Condition Control

7.3.3.3.3.1 coreN_IRQn

Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (Group *N* Interrupt Map Register (Base Address + 0x200 + N*0x20 + 0x18)) and is enabled (Group *N* Interrupt Enabled Set Register (Base Address + 0x200 + N*0x20 + 0x08)), and its priority is not masked (4.1.11 IRQ Priority Mask Register (Base Address + 0x28), and it is not masked because of nested interrupt priority masking (2.2.5 Priority Interrupt / Nested Interrupts), then it will cause an IRQ to assert.

7.3.3.3.3.2 coreN_FIQn

Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ (Group *N* Interrupt Map Register (Base Address + 0x200 + N*0x20 + 0x18)) and is enabled (Group *N* Interrupt Enabled Set Register (Base Address + 0x200 + N*0x20 + 0x08)), and its priority is not masked (4.1.12 FIQ Priority Mask Register (Base Address + 0x2C)), and it is not masked because of nested interrupt priority masking (2.2.5 Priority Interrupt / Nested Interrupts), then it will cause an FIQ to assert.

7.3.3.3.4 Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM software wants to take advantage of. For IRQs, it is recommended to use 3.4.1 IRQ through the Vector

Copyright © 2026 Texas Instruments Incorporated

Interface, but 3.4.2 or 3.4.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives. For FIQs, it is recommended to use 3.4.4 FIQ, but 3.4.5 may be used as an alternative.

Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

7.3.3.3.4.1 IRQ through the Vector Interface

If the attached CPU has the Vector Interface enabled, then the following method is used for servicing IRQs

1. Hardware handshake
   a. CPU asserts coreN_IRQACK signal high
   b. VIM asserts coreN_IRQADDRV to indicate that the coreN_IRQADDR bus is stable with the correct Vector Address
   c. CPU reads the coreN_IRQADDR, jumps to that address, and de-asserts coreN_IRQACK signal low
   d. VIM de-asserts coreN_IRQn_intr and coreN_IRQADDRV, VIM masks all IRQs with the same or lower priority
   e. VIM loads the value from the Prioritized IRQ (Base Address + 0x08) (which corresponds to the vector address) to be loaded into the Active IRQ (Base Address + 0x20) and the valid bit to be set
2. Service an interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active IRQ (Base Address + 0x20) to determine number and reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
         2. If the source maintains the level, then it means there is another interrupt

4. 4. Write any value to the IRQ Vector Address (Base Address + 0x18)
   a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
   b. This will clear the valid bit of the Active IRQ (Base Address + 0x20)

7.3.3.3.4.2 IRQ through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the Vector Interface.

1. Read the IRQ Vector Address (Base Address + 0x18) and jump to that address to service the ISR

Copyright © 2026 Texas Instruments Incorporated

a. Reading this register will mask all interrupts of an equal or lower priority and de-assert the IRQn output. If another interrupt of a higher priority becomes available, the IRQn will re-assert, allowing priority interruption of an interrupt.
b. Reading this register will cause the value from the Prioritized IRQ (Base Address + 0x08) (which corresponds to the vector address) to be loaded into the Active IRQ (Base Address + 0x20) and the valid bit to be set

2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active IRQ (Base Address + 0x20) to determine number and reading the Group M Type Map Register (Base Address + 0x200 + M*0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
         2. If the source maintains the level, then it means there is another interrupt

4. Write any value to the IRQ Vector Address (Base Address + 0x18)
   a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
   b. This will clear the valid bit of the Active IRQ (Base Address + 0x20)

7.3.3.3.4.3 IRQ through MMR Interface (Alternative)

If a user does not want to use the Vector Address registers, the VIM may be used as a more traditional interrupt controller. Note that in this mode, priority masking will not work if route 1b is used (below) as the hardware prioritization may not match the software prioritization scheme. In this case, software would be responsible for doing all priority operations

1. Determine which interrupt to service
   a. Read the Prioritized IRQ (Base Address + 0x08) to determine which interrupt is the highest priority IRQ currently asserted OR
   b. Optionally read the IRQ Group Status (Base Address + 0x10) to determine which groups have IRQs pending, then read the Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10) and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Read the IRQ Vector Address (Base Address + 0x18)
   a. Note, this step can be done any time before step 4
   b. Value is ignored
4. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)

Copyright © 2026 Texas Instruments Incorporated

a. Pulse
   i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
   ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

b. Level
   i. Clear the interrupt at the source
   ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt

5. Write any value to the IRQ Vector Address (Base Address + 0x18)

7.3.3.3.4.4 FIQ

When an FIQ interrupt is received, the CPU should follow these steps.

1. Read the FIQ Vector Address (Base Address + 0x1C) and jump to that address to service the ISR
   a. Reading this register will mask all interrupts of an equal or lower priority and de-assert the FIQn output. If another interrupt of a higher priority becomes available, the FIQn will re-assert, allowing priority interruption of an interrupt.
   b. Reading this register will cause the value from the Prioritized FIQ (Base Address + 0x0C) (which corresponds to the vector address) to be loaded into the Active FIQ (Base Address + 0x24) and the valid bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active FIQ (Base Address + 0x24) to determine number and reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
         2. If the source maintains the level, then it means there is another interrupt

4. Write any value to the FIQ Vector Address (Base Address + 0x1C)

Copyright © 2026 Texas Instruments Incorporated

a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
b. This will clear the valid bit of the Active FIQ (Base Address + 0x24)

7.3.3.3.4.5 FIQ (Alternative)

If a user does not want to use the Vector Address registers, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the FIQ Vector Address (Base Address + 0x1C) is never read). Software would be responsible for doing all priority operations

1. Determine which interrupt to service
   a. Read the Prioritized FIQ (Base Address + 0x0C) to determine which interrupt is the highest priority FIQ currently asserted OR
   b. Optionally read the FIQ Group Status (Base Address + 0x14) to determine which groups have IRQs pending, then read the Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14) and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
         2. If the source maintains the level, then it means there is another interrupt

7.3.3.4 Memory Map

Each Interrupt Core (*N* = 0) has its own MMR interface with its own independent memory map

Table 7-20. Core *N* Memory Map

Address Offset	Register
0x00	Revision Register
0x04	Info Register
0x08	Prioritized IRQ
0x0C	Prioritized FIQ
0x10	IRQ Group Status
0x14	FIQ Group Status
0x18	IRQ Vector Address
0x1C	FIQ Vector Address
0x20	Active IRQ
0x24	Active FIQ
0x28-0x2F	*Reserved*

Copyright © 2026 Texas Instruments Incorporated

Table 7-20. Core *N* Memory Map (continued)

Address Offset	Register
0x30	DED Vector Address
0x34-0x1FF	*Reserved*
0x400 + *M**0x20 + 0x00	Group *M* Interrupt Raw Status/Set Register
0x400 + *M**0x20 + 0x04	Group *M* Interrupt Enabled Status/Clear Register
0x400 + *M**0x20 + 0x08	Group *M* Interrupt Enabled Set Register
0x400 + *M**0x20 + 0x0C	Group *M* Interrupt Enabled Clear Register
0x400 + *M**0x20 + 0x10	Group *M* Interrupt IRQ Enabled Status/Clear Register
0x400 + *M**0x20 + 0x14	Group *M* Interrupt FIQ Enabled Status/Clear Register
0x400 + *M**0x20 + 0x18	Group *M* Interrupt Map Register
0x400 + *M**0x20 + 0x1C	Group *M* Type Map Register
0x1000 + *Q**0x4 – 00x1FFF	Interrupt *Q* Priority Register
0x2000 + *Q**0x4 – 0x2FFF	Interrupt *Q* Vector Register

There are *M* interrupt groups (0 through *num_groups*-1) with 32 interrupts per group.

There are *Q* interrupt inputs where *Q* = *M* * 32.

Accesses to the Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q**0x4) must be word-aligned, 32-bit accesses. Any write received with no bytes enabled will be ignored. Any writes receive with all bytes enabled will be executed. Any other write will not execute and will return an error status of Addressing Error.

7.3.3.5 Module I/O

7.3.3.5.1 Clocks, Reset, Emulation

Table 7-21. Clocks, Reset, Emulation

Pin Name	Type	Function
core0_clk	In	Clock for Core 0
core0_phase	In	Phase Indicator for Core 0

7.3.3.6 Programmer's Guide

7.3.3.6.1 Initialization Sequence

At initialization, the following tasks should be performed:

1. Program the DED Vector Address (Base Address + 0x30)
2. Program Group *M* Interrupt Map Register (Base Address + 0x200 + *M**0x20 + 0x18)
3. Program Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C)
4. Program Interrupt *Q* Priority Register (Base Address + 0x1000 + *Q**0x4)
5. Program Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q**0x4)
6. Enable interrupts via the Group *M* Interrupt Enabled Set Register (Base Address + 0x400 + *M**0x20 + 0x08)

Note that the Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q**0x4) for each interrupt that will be enabled must be written before the interrupt is enabled, even if software is not going to use the vector. Whenever an interrupt is prioritized, the RAM location for the interrupt is read, and if that location is un-initialized, an ECC error will be reported. If the vectors aren't being used, then the RAM can be initialized by writing 0x0 to every location.

7.3.3.6.2 DED Behavior

Whenever there is 2-bit error detect on a Vector Address, the DED Vector Address (Base Address + 0x30) overrides all other vectors. Software should provide an ISR to handle this scenario at this address.

7.3.3.6.3 Power Up/Down Sequence

Before a clean power down, software should check that there are no pending interrupts, disable all interrupts, and wait for the clkstop_idle output.

7.4 Device Manager Cortex R5F Subsystem (WKUP_R5FSS)

This chapter describes the Arm Cortex R5F real-time microcontroller unit subsystem (WKUP_R5FSS) in the device.

7.4.1 WKUP_R5FSS Overview

The WKUP_R5FSS is a single-core implementation of the Arm® Cortex®-R5F processor that acts as the Device Manager responsible for boot, resource management, and power management functions. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm CoreSight™ debug and trace architecture, integrated vectored interrupt manager (VIM), ECC aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

Copyright © 2026 Texas Instruments Incorporated

Note

The Cortex-R5F processor is a Cortex-R5 processor that includes the optional floating point unit (FPU) extension. In this TRM, all references to the Cortex-R5 processor apply to the Cortex-R5F processor by default.

There is one WKUP_R5FSS subsystem in the device. Table 7-30 shows WKUP_R5FSS allocation across device domains.

Table 7-30. R5FSS Allocation Across Device Domains

Module Instance	Domain		
	MCU	MAIN	WKUP
WKUP_R5FSS	–	–	✓

7.4.1.1 WKUP_R5FSS Features

The WKUP_R5FSS supports the following features:

- Single-core Arm Cortex-R5F
  - Core revision: r1p3
  - Armv7-R profile
  - L1 memory system
    - 32KB instruction cache
      - 4x8KB ways
      - SECDED ECC protected per 64 bits
    - 32KB data cache
      - 4x8KB ways
      - SECDED ECC protected per 32 bits
    - 64KB tightly-coupled memory (TCM)
      - SECDED ECC protected per 32 bits
      - TCM hard error cache Implemented in CPU
      - Readable/writable from system
      - TCMs initialized (to 0's) at reset
      - Split into A and B banks (with B further splitting into B0 and B1 interleaved banks)
        - 32KB TCMA (ATCM)
        - 16KB TCMB0 (B0TCM)
        - 16KB TCMB1 (B1TCM)
  - Low interrupt latency with restartable instructions
  - Non-maskable interrupt (NMI)
  - Full-precision floating point (VFPv3)
  - 16 region memory protection unit (MPU)
  - 8 breakpoints
  - 8 watchpoints
  - Dynamic branch prediction with global history buffer and 4-entry return stack
  - CoreSight debug access port (DAP)
  - CoreSight embedded trace macrocell (ETM-R5) interface
  - Performance monitoring unit (PMU)
- Interfaces
  - 64-bit VBUSM initiator pair (1 read, 1 write) for L3 memory accesses
  - 64-bit VBUSM target for TCM access
    - Also allows access to cache for debug purposes
  - 32-bit VBUSP initiator for peripheral access
  - 32-bit VBUSP target configuration port
  - 32-bit VBUSP target debug port

Copyright © 2026 Texas Instruments Incorporated

        - Allows access to all WKUP_R5FSS internal debug logic
    - ECC/Parity support on all internal SoC bus interfaces
    - ECC/Parity support on internal SoC bus bridges
- Synchronous clock domain crossing on all interfaces
    - Interfaces can run at an integer multiple of the core frequency
- 32-bit to 36-bit region-based address translation (RAT) on memory access initiators
    - 4 regions
        - Base address + size
        - Must be size aligned
- Integrated vectored interrupt manager (VIM)
    - 256 interrupts
        - Each interrupt programmable as either IRQ or FIQ
        - Each interrupt has a programmable enable mask
        - Each interrupt has a programmable 4-bit priority
    - Priority interrupt supported
    - Vectored interrupt interface
        - Compatible with R5F VIC port
        - Programmable 32-bit vector address per interrupt
            - Address is SECDED error protected
            - Default vector addresses provided on DED
        - Software interrupt generation
- Integrated ECC aggregators
    - Support for error injection to all supported ECC memory blocks to test ECC functionality (add-on function from TI)
    - One ECC aggregator to cover all RAMs and caches
- Standard Arm CoreSight debug and trace architecture at the R5FSS level
    - Cross triggering: Supported by cross trigger interface (CTI) (per CPU) and cross trigger matrix (CTM) components
    - Processor trace: Supported by embedded trace macrocell (ETM) (per CPU) and advanced trace bus (ATB) funnel components
- Boot
    - From ROM only

See Section 7.4.2 for a functional block diagram and more details on the WKUP_R5FSS.

Note

Some features may not be available. See *Module Integration* for more information.

Copyright © 2026 Texas Instruments Incorporated

7.4.2 WKUP_R5FSS Functional Description

7.4.2.1 WKUP_R5FSS Block Diagram

Figure 7-12 shows the WKUP_R5FSS block diagram.

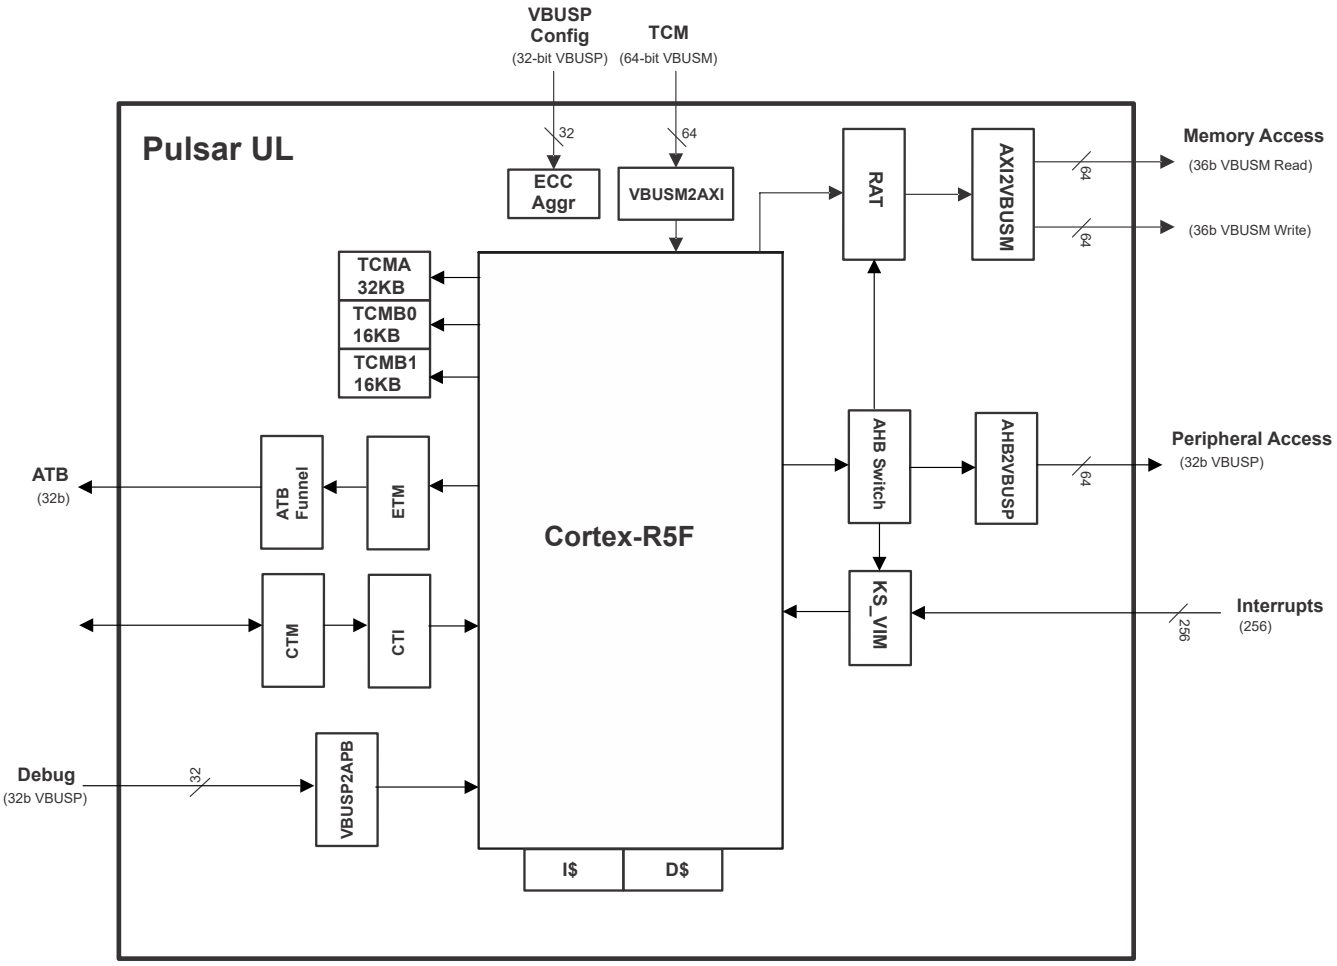

Figure 7-12. WKUP_R5FSS Block Diagram

7.4.2.2 WKUP_R5FSS Cortex-R5F Core

The Cortex-R5F is a processor from Arm, which is based on the Armv7-R profile.

For a brief list of features supported by the R5F processor in this device, see Section 7.4.1.1. For more detailed description of this processor, see the *Arm Cortex-R5 Technical Reference Manual*.

7.4.2.2.1 L1 Caches

The R5F has a Harvard cache architrecture, which means it has an independent L1 instruction cache (16KB) and L1 data cache (16KB). The instruction cache is protected by SECDED ECC per 64 bits. The data cache is protected by SECDED ECC per 32 bits.

7.4.2.2.2 Tightly-Coupled Memories (TCMs)

The R5F has two tightly-coupled memories (TCMs), ATCM and BTCM. The BTCM is further broken down into two interleaved banks, B0TCM and B1TCM.

TCMs are low-latency, tightly integrated memories for the R5F to use. Either TCM can be used for any combination of instruction and/or data. TCM performance is equal to performance on instructions/data that are in cache. However, TCMs have some additional advantages over cache. TCMs can be loaded with instructions

Copyright © 2026 Texas Instruments Incorporated

that do not cache well (such as ISRs) or preloaded with code by an external source, before that code is needed, to save cache miss time. TCMs are also a good place for blocks of data for intense processing. They can be loaded (or pre-loaded by an external source) before the data is needed, saving cache miss time. The data can then be directly accessed by an external source, instead of needing to do cache evicts.

As mentioned, TCMs can be accessed (either read or written) by an external source over the TCM VBUSM target interface. This allows instructions or data to be preloaded, or for data to be read out after the R5F has processed it. The VBUSM target has a lower priority to accessing TCMs than the R5F but care must be taken to keep an external source from reading or writing TCM data that the R5F is working on. This handshaking is external to any of the R5FSS hardware.

TCMs are protected by ECC per 32 bits. For this to work, ECC must be enabled before data is written in to the TCMs (either externally or from the R5F). ECC is enabled via the following R5F system control bits: ACTLR.ATCMPCEN, ACTLR.B0TCMPCEN, and ACTLR.B1TCMPCEN, respectively.

Whether or not the TCMs are enabled is controlled by the ENABLE bit in the corresponding ATCM/BTCM region register. The default (reset) value of this bit is determined by the CPUn_INITRAMA and CPUn_INITRAMB bootstraps, respectively. Both ATCM and BTCM are configured for a size of 32KB in this device. Note that the BTCM size is the total of both B0TCM and B1TCM (16KB each).

If a TCM is not enabled, then it does not appear in the R5F's memory view, but it can be accessed by an external source. If a TCM is enabled, then its place in the R5F memory map is determined by a combination of bootstrap signal and system register. If the CPUn_LOCZRAMA bootstrap signal is high, then the initial base address of ATCM is 0x0000_0000 and the initial address of BTCM is 20'h41010. If the CPUn_LOCZRAMA bootstrap signal is low, then the initial base address of BTCM is 0x0000_0000 and the initial base address of ATCM is 20'h41010.

Note

This base address of 0x41010 for ATCM/BTCM based on the CPUn_LOCZRAMA bootstrap only affects the R5F's memory view. The SoC will see the ATCM/BTCM based on the TCM target interface regions, as defined in Section 7.4.2.3.2. The base address of either TCM may be overwritten via the ATCM or BTCM region register. Care must be taken not to move the base address of a TCM when it may be being accessed.

It is possible to preload a TCM with instructions and boot from it. See Section 7.4.2.11 for details on TCM booting.

7.4.2.2.3 WKUP_R5FSS Special Signals

Table 7-31 lists some WKUP_R5FSS features associated with special signals.

Table 7-31. WKUP_R5FSS Special Features

Feature	Comment
Cluster affinity group ID	R5F Cluster 0 (ID = 0x0)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
CPUn execution halt when coming out of reset (CPUn_HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPUn exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPUn VIM base address	0x2FFF_0000
CPUn RAT base address	0x2FFE_0000
CPUn RAT accesses ID	0x4 (CPU0)
CPUn ATCM enable at reset (CPUn_INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state

Copyright © 2026 Texas Instruments Incorporated

Table 7-31. WKUP_R5FSS Special Features (continued)

Feature	Comment
CPUn BTCM enable at reset (CPUn_INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPUn A/BTCM reset base address indicator (CPUn_LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPUn non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPUn VBUSM peripheral port enabled at reset	Enabled
CPUn VBUSP peripheral port enable at reset	Enabled
CPUn VBUSP peripheral port base address	Mapped to 0x0_2000_0000 for low latency MAIN peripherals
CPUn VBUSP peripheral port size	64MB for MAIN peripherals (0x0_2000_0000 to 0x0_2FFF_FFFF)
CPUn VBUSM normal peripheral port base address	Not used
CPUn VBUSM normal peripheral port size	Not used
CPUn VBUSM virtual peripheral port base address	Not used
CPUn VBUSM virtual peripheral port size	Not used
CPUn clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPUn WFI state	Status logged into MAIN_SEC_MMR register bit
CPUn WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

7.4.2.3 WKUP_R5FSS Interfaces

7.4.2.3.1 Initiator Interfaces

The WKUP_R5FSS has several initiator interfaces:

- 64-bit VBUSM initiator pair (1 read - "RMST", 1 write - "WMST") for L3 memory accesses; this is the main memory interface
  - Includes region-based address translation (RAT)
- 32-bit VBUSP initiator "PMST" for peripheral access
  - Includes logic that provides the R5F CPU with a private access to VIM and RAT
  - Enabled at reset

7.4.2.3.2 Target Interfaces

The WKUP_R5FSS has several target interfaces that define its internal memory space:

- 32-bit VBUSP configuration target
  - Region [0]: ECC aggregator block
- 64-bit TCM target
  - Region [0]: ATCM
  - Region [1]: BTCM
  - Region [2]: Instruction cache RAMs
  - Region [3]: Data cache RAMs
- 32-bit VBUSP debug target
  - Provides access to all R5FSS internal debug logic

Regions [0] and [1] of the TCM target interface provide direct access to the TCM RAMs. Access to the RAMs is arbitrated with access from the R5F's L1 memory system. Excessive access while the R5F is also attempting access will degrade performance.

Regions [2] and [3] of the TCM target interface provide access to the cache RAMs for testing purposes. Access to the cache RAMs can only be done while the caches are disabled and should only be done for test purposes.

Copyright © 2026 Texas Instruments Incorporated

In addition to the target interfaces, there are peripherals (RAT and VIM) that are only accessible by the R5F. The R5F has an access to these modules via the VBUSP peripheral interface.

7.4.2.4 WKUP_R5FSS Power, Clocking and Reset

7.4.2.4.1 WKUP_R5FSS Power

The following WKUP_R5FSS power considerations should be noted:

- WKUP_R5FSS has a single power domain for all its internal logic

For more details on WKUP_R5FSS power management, including power-up and power-down sequences, see *Power*.

7.4.2.4.2 WKUP_R5FSS Clocking

The WKUP_R5FSS has four clock inputs:

- CPU0_CLK: This is the clock for CPU0 logic
- CPU0_ICLK: This is the clock for CPU0 interfaces

CPU0_CLK is the clock for all of the internal CPU logic, while CPU0_ICLK is the clock for all of the interfaces for their associated CPU (for example: VBUSM and VBUSP bridges, exception generation, debug and trace logic).

The interface clock is an integer ratio of the CPU clock. The exact ratio for this device is 1:1.

7.4.2.4.3 WKUP_R5FSS Reset

The R5FSS has two reset inputs:

- CPU0_RST: This is the reset for the non-debug logic of CPU0
- CPU0_DBG_RST: This resets the CPU0 debug logic, excluding the APB interface

In addition to the reset signals, there is one halt signal:

- CPU0_HALT

These halt signals keep the CPUs from fetching instructions when they come out of reset. The main use is to have the CPUs halted until the TCMs are loaded (when booting from TCM), though halt could be used for any other purpose.

7.4.2.5 WKUP_R5FSS Vectored Interrupt Manager (VIM)

7.4.2.5.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU. It can be used in either split or single-core configuration.

The VIM module supports the following features:

- 256 interrupt inputs for the R5F core
- Each interrupt has its own 4-bit programmable priority
  - Defined via the R5FSS_VIM_PRI_INT_j register
  - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
  - Interrupt enable is done via the R5FSS_VIM_INTR_EN_SET_j register
  - Interrupt disable is done via the R5FSS_VIM_INTR_EN_CLR_j register
- Each interrupt can be programmed as either an IRQ or FIQ
  - Defined via the R5FSS_VIM_INTMAP_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
  - Defined via the R5FSS_VIM_VEC_INT_j register
  - Protected with SECDED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
  - Compatible with R5F VIC port

Copyright © 2026 Texas Instruments Incorporated

- Default vector provided when a double-bit error is detected
- Software interrupt generation

7.4.2.5.2 VIM Interrupt Inputs

The VIM supports 256 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the R5F core can be found in *Interrupt Sources*.

7.4.2.5.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- *CoreN_IRQn*: This is a normal interrupt for core *N* (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the R5FSS_VIM_INTMAP_j register) and is enabled (via the R5FSS_VIM_INTR_EN_SET_j register), then it will cause an IRQ to assert
- *CoreN_FIQn*: This is a fast (or non-maskable) interrupt for core *N* (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

7.4.2.5.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (R5FSS_VIM_VEC_INT_j). Hence, the interrupt vector table is organized in 256 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

Note

The lower two bits of the 32-bit interrupt vector are always 0s.

Figure 7-13 shows the VIM RAM interrupt vector map.

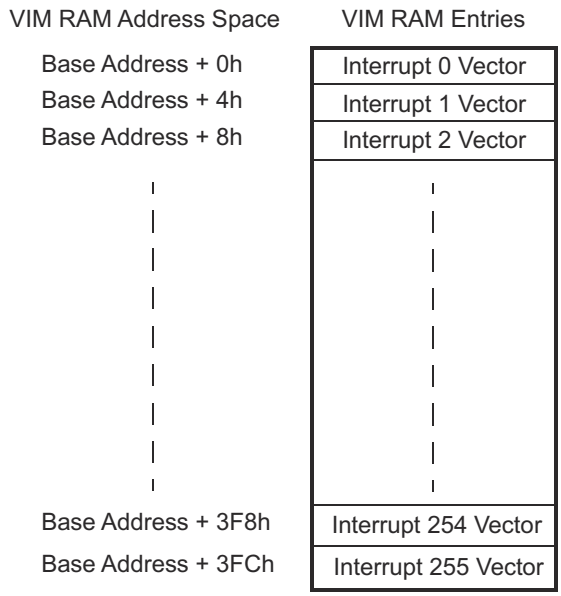

Figure 7-13. VIM RAM Interrupt Vector Map

Copyright © 2026 Texas Instruments Incorporated

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. See Table 7-34 for the VIM RAM ID in the ECC aggregator map.

7.4.2.5.5 VIM Interrupt Prioritization

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the R5FSS_VIM_FIQVEC register; IRQ: reading the R5FSS_VIM_IRQVEC register, or the *coreN_IRQACK* going high), then the interrupt is loaded into the corresponding active register (R5FSS_VIM_ACTFIQ / R5FSS_VIM_ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to the R5FSS_VIM_FIQVEC register, or R5FSS_VIM_IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. If the CPU switches this interrupt to active (by reading the R5FSS_VIM_FIQVEC / R5FSS_VIM_IRQVEC register), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by reading the R5FSS_VIM_FIQVEC / R5FSS_VIM_IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the R5FSS_VIM_ACTFIQ / R5FSS_VIM_ACTIRQ register, so that software may continue where it left off.

7.4.2.5.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the R5FSS_VIM_DEDVEC register is used to provide the default vector for the *coreN_IRQADDRV* signal, the R5FSS_VIM_IRQVEC register, and the R5FSS_VIM_FIQVEC register. The R5FSS_VIM_DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
   a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device
4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt . This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by the R5FSS ECC aggregator.

7.4.2.5.7 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

7.4.2.5.8 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in Section 7.4.2.5.8.1, but the procedures in Section 7.4.2.5.8.2 or Section 7.4.2.5.8.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

Copyright © 2026 Texas Instruments Incorporated

For FIQs, it is recommended to use the procedure in Section 7.4.2.5.8.4, but the procedure in Section 7.4.2.5.8.5 may be used as an alternative.

Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

7.4.2.5.8.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
   a. CPU asserts *coreN_IRQACK* high
   b. VIM asserts *coreN_IRQADDRV* to indicate that the *coreN_IRQADDR* bus is stable with the correct vector address
   c. CPU reads *coreN_IRQADDR*, jumps to that address, and de-asserts *coreN_IRQACK* low
   d. VIM de-asserts *coreN_IRQn* and *coreN_IRQADDRV*, VIM masks (discards) all IRQs with the same or lower priority
   e. VIM loads the value from the R5FSS_VIM_PRIIRQ[9:0] NUM bit field (which corresponds to the vector address) into the R5FSS_VIM_ACTIRQ[9:0] NUM bit field, which causes the R5FSS_VIM_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS_VIM_ACTIRQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS_VIM_INTTYPE_j register to determine type)
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_IRQSTS_j register, or R5FSS_VIM_STS_j register
      ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_IRQSTS_j register, or R5FSS_VIM_STS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS_VIM_IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTIRQ[31] VALID bit

7.4.2.5.8.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the R5FSS_VIM_IRQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN_IRQn* will re-assert, allowing priority interruption of an interrupt
   b. Reading this register will cause the value from the R5FSS_VIM_PRIIRQ[9:0] NUM bit field to be loaded into the R5FSS_VIM_ACTIRQ[9:0] NUM bit field, and the R5FSS_VIM_ACTIRQ[31] VALID bit to be set

Copyright © 2026 Texas Instruments Incorporated

2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
      ii. Clear the interrupt at the source
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
4. Write any value to the R5FSS_VIM_IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTIRQ[31] VALID bit

7.4.2.5.8.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the R5FSS_VIM_IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS_VIM_IRQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the R5FSS_VIM_PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
   b. Optionally read the R5FSS_VIM_IRQGSTS register to determine which groups have IRQs pending, then read the R5FSS_VIM_IRQSTS_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
      ii. Clear the interrupt at the source.
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register

7.4.2.5.8.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the R5FSS_VIM_FIQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN_FIQn* will re-assert, allowing priority interruption of an interrupt.
   b. Reading this register will cause the value from the R5FSS_VIM_PRIFIQ[9:0] NUM bit field to be loaded into the R5FSS_VIM_ACTFIQ[9:0] NUM bit field, and the R5FSS_VIM_ACTFIQ[31] VALID bit to be set
2. Service the interrupt

Copyright © 2026 Texas Instruments Incorporated

3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS_VIM_ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS_VIM_INTTYPE_j register to determine type)
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register
      ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS_VIM_FIQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the R5FSS_VIM_ACTFIQ[31] VALID bit

7.4.2.5.8.5 Servicing FIQ (Alternative)

If a user does not want to use the R5FSS_VIM_FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS_VIM_FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the R5FSS_VIM_FIQVEC register to determine which interrupt is the highest priority FIQ currently asserted, OR
   b. Optionally read the R5FSS_VIM_FIQGSTS register to determine which groups have IRQs pending, then read the R5FSS_VIM_FIQSTS_j register and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register
      ii. Clear the interrupt at the source.
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register.

7.4.2.6 WKUP_R5FSS Region Address Translation (RAT)

7.4.2.6.1 WKUP R5FSS Usage

R5 is a micro controller with 32b address, which is only able to access up to 4GB address space. However, Sitara™ SoC supports 36b address and majority of the memory region beyond lower 4GB are implemented. Region based address translation block, called RAT, is introduced to allow R5 core to access full 36b SoC memory map.

Each R5 core has its own RAT block, and only R5 core itself is able to program the RAT.

Copyright © 2026 Texas Instruments Incorporated

Figure 7-14 shows the main R5's default 32b memory map view when main R5 is out of reset.

The full RAT functionality is described in Section 7.3.2.6.2, *RAT Function*.

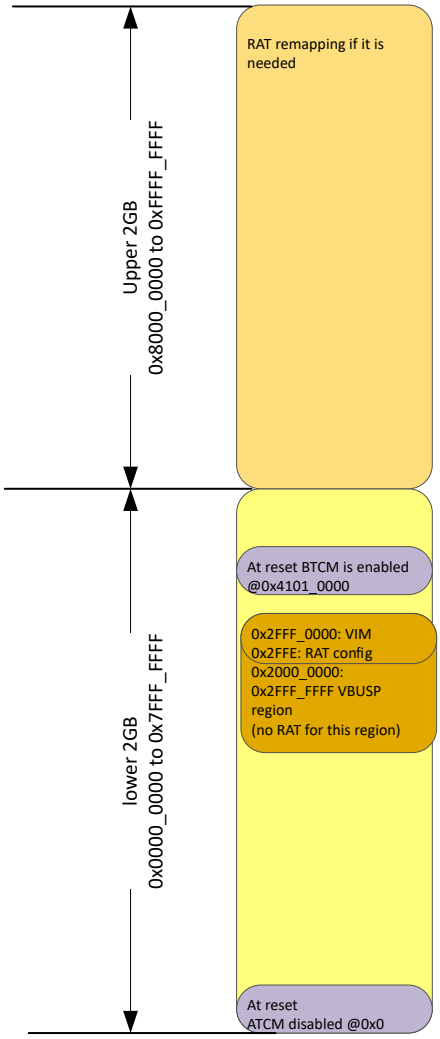

Figure 7-14. R5 Core Default Memory Map View

Copyright © 2026 Texas Instruments Incorporated

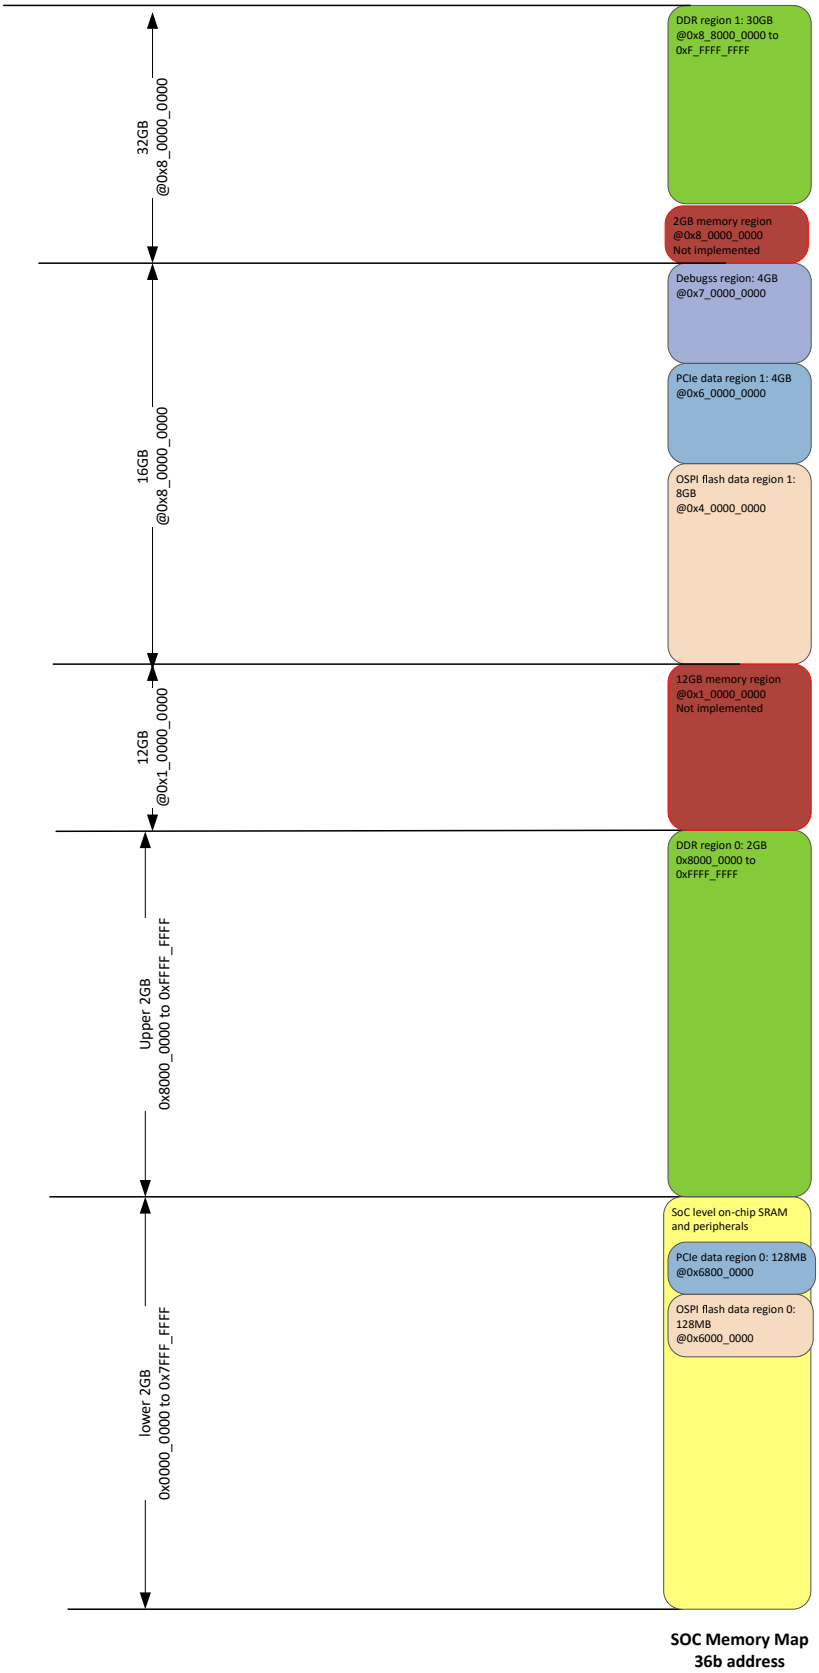

Figure 7-15. Typical Sitara SoC Memory Map View

Copyright © 2026 Texas Instruments Incorporated

RAT block enables R5 core to have full access on the SoC memory map including the memory region at and above 0x1_0000_0000.

Figure 7-16 shows how R5 access various end points, including its own ATCM, BTCM, VIM and SoC memory and peripherals. R5's ATCM is by default at address 0x0, and its BTCM is at address 0x4101_0000. R5 uses address 0x2FFF_0000 to access its VIM and 0x2FFE_0000 to access the RAT configuration region and all the other transactions between address range 0x2000_0000 to 0x2FFF_FFFF are sent to the 32b peripheral interface to access the peripherals in SoC. The transactions with the rest of address are sent to RAT block, which could go through address remapping function from original R5's 32b address to 36b SoC address.

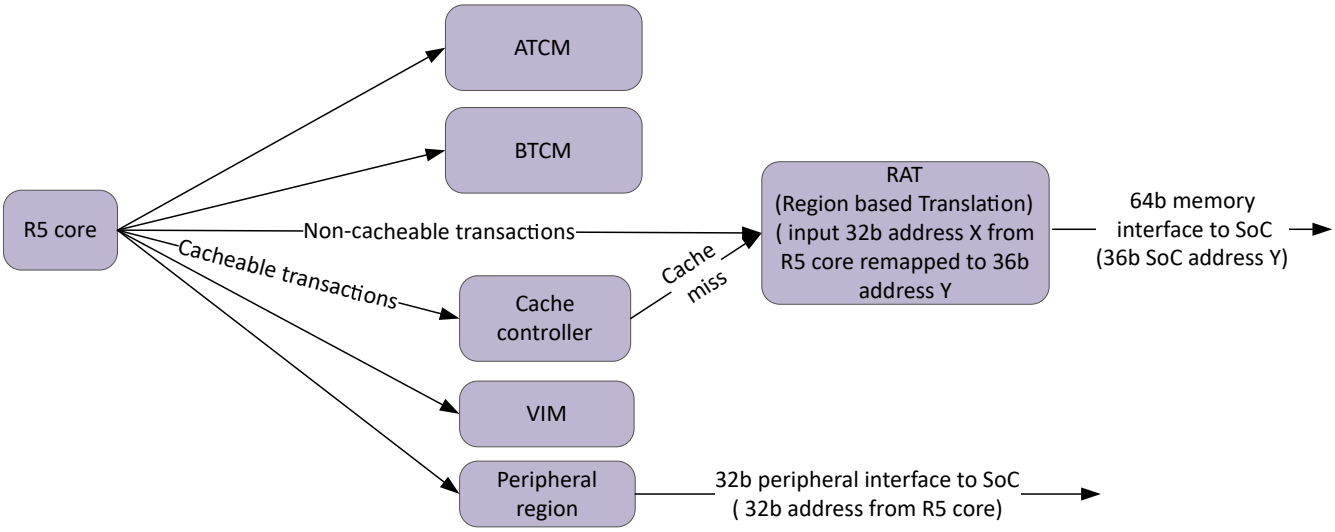

Figure 7-16. R5 Internal Address Decoding

7.4.2.6.2 RAT Function

RAT block is responsible to do a region based address translation. For each region, user can define the starting address and size of the region and remapping the transactions to use a new address range.

The starting address and region size need to be aligned. For example, if the region size is 16KB, the starting address for that region needs to be 16KB aligned. And region size should be minimum 4KB or larger to avoid transactions cross the region boundaries.

Each RAT block supports multiple programmable regions. And it is important that those regions are not overlapping with each other.

RAT block is by default disabled, which means RAT block does not do address remapping. The 32b address coming from R5 core is directly sent out to the SoC level. The user can program each RAT remapping region individually. For the transactions does not hit any remapping region, RAT block just simply forwards the transactions to the SoC level with its original address.

7.4.2.6.3 How to use RAT Block in R5

Table 7-32 shows the default R5 memory map view. Without enabling RAT function, all the regions beyond 4GB address space will not be accessible by R5.

Sitara™ SoC memory map is constructed the way to allow R5 and high level application processor such as A53 have similar memory map as possible. This methodology enables that R5 and ARM A53 core have a common memory map for all the SoC level memories and SoC level peripherals except a few exceptions:

- DDR's data space beyond 32b address, basically upper DDR data space beyond 2GB
- PCIe data space beyond 32b address
- OSPI data space beyond 32b address
- Debug configuration region

Copyright © 2026 Texas Instruments Incorporated

Table 7-32. R5 Memory map by Default

	R5 Memory Map(32b)	SoC Memory Map (36b)
SoC Level peripheral and on-chip SRAM	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF
2GB DDR region	Same as SoC memory map: 0x8000_0000 to 0xFFFF_FFFF	0x80000_0000 to 0xFFFF_FFFF
Additional DDR region	Not accessible	0x8_8000_0000 (30GB)
Additional 8GB OSP Space	Not accessible	0x4_0000_0000 (4GB) 0x5_0000_0000 (4GB)
Additional PCIe data space	Not accessible	0x6_000_0000
Debug configuration region	Not accessible	0x7_0000_0000

Even though all the transactions other than going to ATCM/BTCM and transactions between address range 0x2000_0000 to 0x2FFF_FFFF could use RAT block to remap to different address, it is recommended that only use RAT block to remap the R5 transactions with address between 0x8000_0000 to 0xFFFF_FFFF.

- Any transactions from R5 with address between 0x0 to 0x7FFF_FFFF are sent out to SoC directly (unless it is targeted to its internal end points such as A/B TCM, its VIM and RAT configuration)
- Only enable RAT to remap the transactions with address between 0x8000_0000 to 0xFFFF_FFFF if R5 needs to access the following address space:
  - PCIe data space at address 0x6_0000_0000
  - OSPI data space address 0x4_0000_0000 and 0x5_0000_0000
  - Debug configuration region at address 0x7_0000_0000
  - DDR data space at address 0x8_8000_0000

Copyright © 2026 Texas Instruments Incorporated

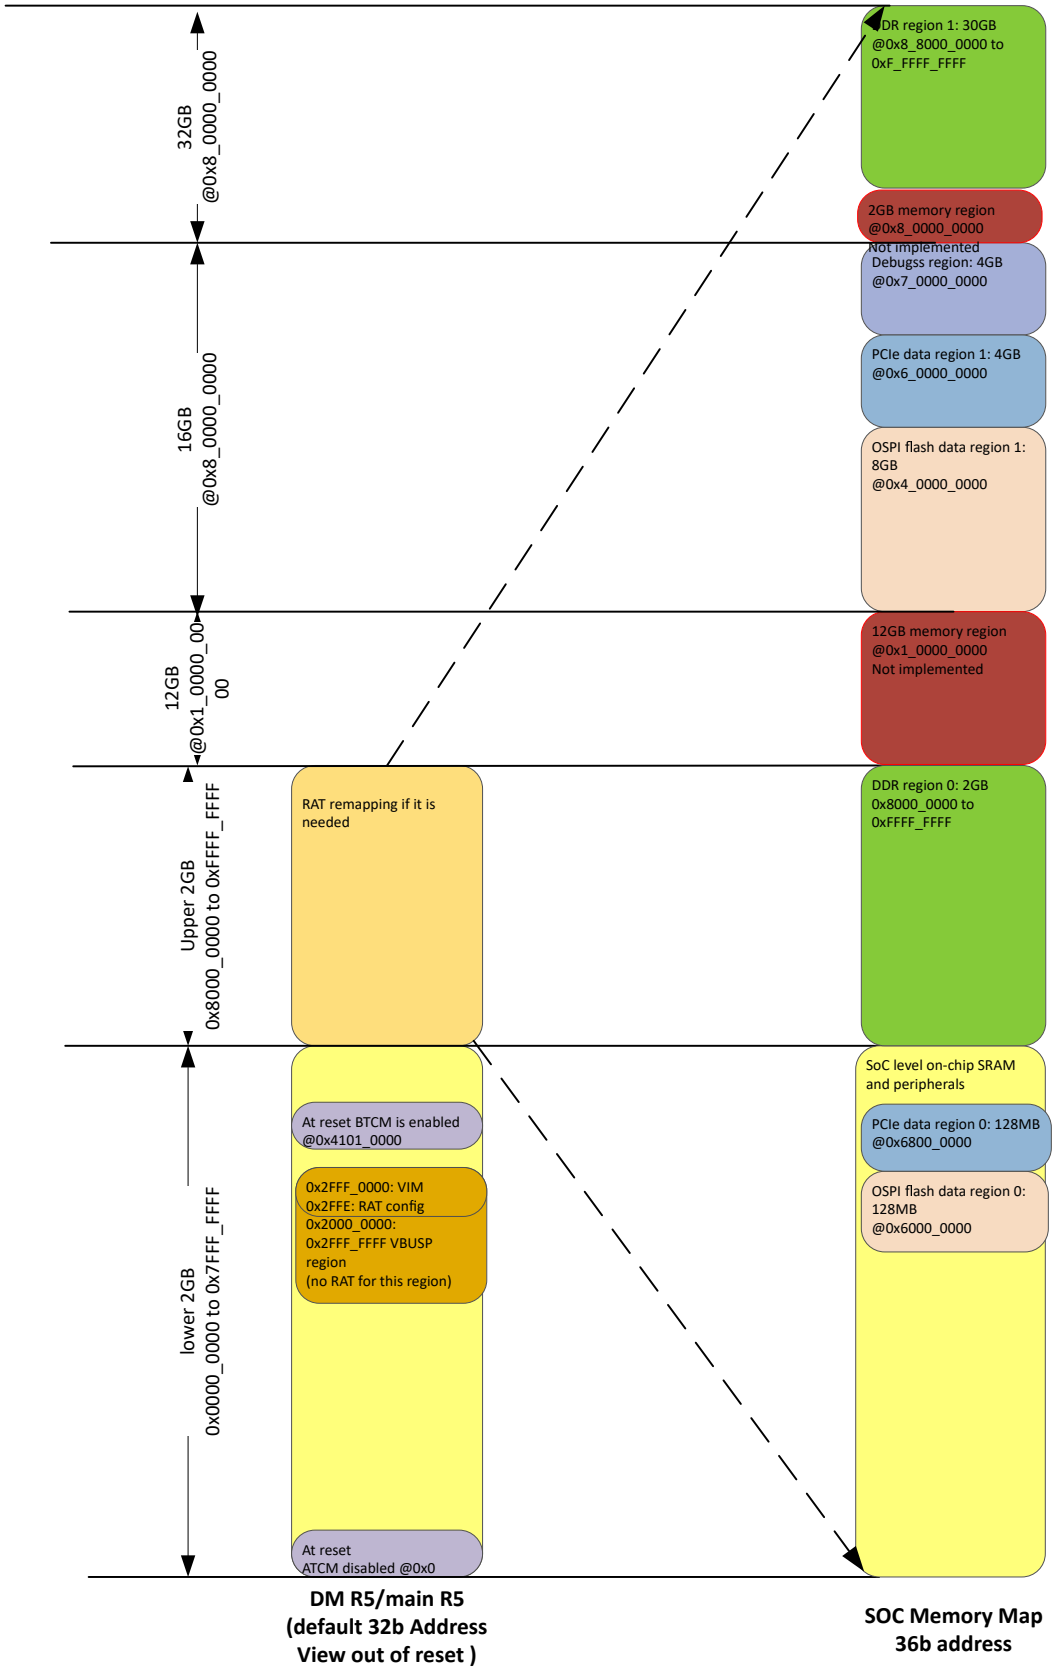

Figure 7-17. Example of Using RAT to Access Full 36b SoC Memory Map

Copyright © 2026 Texas Instruments Incorporated

7.4.2.6.4 Example of Using RAT to Access Full 36b SoC Memory Map

This section shows an example on how to utilize RAT block to allow R5 to access 36 SoC Memory Map. The RAT block inside R5 has up to 8 address remapping regions.

Assuming R5 needs to access the following region:

- All the SoC level on-chip SRAM
- All the SoC level peripherals
- Access 512MB OSPI region at address 0x4_0000_0000
- Access 1GB DDR region at address 0x9_0000_0000
- Access 512MB DDR region at address 0x8000_0000

First of all, we need to construct 32b R5 memory map as following and how those memory spaces are mapped to SoC level, shown in Table 7-33. Users can define where the OSPI and DDR data space placed inside R5's memory map and how they should be mapped to SoC level address map. Table 7-33 just shows one of the many possible ways to construct the memory map.

Table 7-33. Example of R5 Address Mapping

	R5 Memory Map(32b)	SoC Memory Map (36b)	RAT Remapping
SoC Level peripheral and on-chip SRAM (This is guaranteed by SoC Hardware design. No user configuration is needed)	0x0 to 0x7FFF_FFFF Same address as SoC memory map	0x0 to 0x7FFF_FFFF	Not RAT Remapping
512MB OSPI data region (user defined)	0x8000_0000 to 0x9FFF_FFFF	0x4_0000_0000 to 0x4_1FFF_FFFF	Using RAT remapping region 0
512MB DDR space (user defined)	0xA000_0000 to 0xBFFF_FFFF	0x8000_0000 to 0x9FFF_FFFF	Using RAT remapping region 1
Additional 1GB DDR Space (user defined)	0xC000_0000 to 0xFFFF_FFFF	0x9_0000_0000 to 0x9_3FFF_FFFF	Using RAT remapping region 2

In this example, only three RAT regions are needed:

- Region 0 is used to remap R5's address between 0x8000_0000 to 0x9FFF_FFFF to SoC level address 0x4_0000_0000 to 0x4_1FFF_FFFF
- Region 1 is used to remap R5's address between 0xA000_0000 to 0xBFFF_FFFF to 0x8000_0000 to 0x9FFF_FFFF
- Region 2 is used to remap R5's address 0xc000_0000 t0 0xFFFF_FFFF to 0x9_0000_0000 to 0x9_3FFF_FFFF.

In order achieving those mappings, those are the setting of the RAT configuration registers:

	Region 0	Region 1	Region 2	Other regions
Region control register	Enabled, size set to 512MB	Enabled, size set to 512MB	Enabled, size set to 1GB	disabled
Region base(32b)	0x8000_0000	0xA000_0000	0xc000_0000	Don't care
Region translated lower address(32b)	0x0000_0000	0x8000_0000	0x0000_0000	Don't care
Region translated upper address	0x4	0x0	0x9	Don't care

Figure 7-18 shows how RAT is remapping the address between R5's 32b address to 36b SoC address.

7.4.2.7 WKUP_R5FSS ECC Support

The R5F provides native ECC and parity support on all related memories, generating and checking the redundancy automatically. The R5F can also monitor any ECC errors on it's SoC buses and bridges through the ECC aggregator. The methods for checking and reporting errors are available in the *Arm Cortex-R5 Technical Reference Manual*.

The R5FSS adds the capability of testing this logic by allowing errors (single and double bit) to be injected into memories (for testing purposes) via an ECC aggregator (per core). Note that because the R5FSS ECC aggregator is only used in error-injection mode, it only supports a subset of the generic ECC aggregator functionality in the device.

For a detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of the WKUP_R5FSS aggregators, see R5FSS_CPU0_ECC_AGGR_CFG_REGS Registers and R5FSS_CPU1_ECC_AGGR_CFG_REGS Registers, respectively.

Table 7-34 provides the RAM ID. This is needed for bit field [10-0] ECC_VECTOR in the corresponding R5FSS_CPU0_VECTOR**R5FSS_CPU0_VECTOR** register (part of the ECC aggregator register space).

Table 7-34. RAM ID Map for ECC Aggregator (Per Core)

RAM ID	Memory Name
0	CPU0 ITAG RAM0
1	CPU0 ITAG RAM1
2	CPU0 ITAG RAM2

7.4.2.8 WKUP_R5FSS Memory View

The memory view of the R5F (that is, the memory map as seen by each R5F) is a function of several things:

- Exception vector bootstrap: The R5F exception table (including boot vector) is always 32 bytes at address 0x00000000 as seen by the R5F. If not booting from a TCM, then boot is done over the main memory interface. The exception vector bootstrap is under software control, which allows these 32 bytes at address 0x00000000 to be remapped somewhere else in the SoC memory map.
- TCM locations: TCMs can be enabled or disabled and located at different places in the memory map, depending on bootstrap configuration. For more details, see Section 7.4.2.2.2.
- Peripheral interface locations: The RF5 natively supports three interfaces for peripheral access. Each can be enabled/disabled and located based on bootstrap configuration. Note that the VBUSP peripheral interface must be enabled in order to use RAT and VIM.
- RAT base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- VIM base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- RAT programming: The RAT can take regions of memory accessible by the main memory interface and map them to different addresses.

The combination of the above determines what the R5F sees where in the memory map, and over what interface different transactions come out. Every transaction that does not directly address a TCM or a peripheral interface comes over the main memory interface. Transactions on the main memory interface can be further remapped with the RAT.

See *Memory Map* for the complete R5F memory view for this device.

7.4.2.9 WKUP_R5FSS Interrupts

All interrupts that are generated by the WKUP_R5FSS are summarized in *Module Integration*, along with their mapping. They can be divided into the following groups:

- R5F CPU internal interrupts: These are described in *Arm Cortex-R5 Technical Reference Manual*.
- ECC aggregator interrupts: These are described in the *ECC Aggregator* chapter.
- RAT exception interrupt: This is described in Section 7.4.2.6.

7.4.2.10 WKUP_R5FSS Debug and Trace

The WKUP_R5FSS supports standard Arm CoreSight debug and trace architecture. For more details, see the *On-chip Debug* chapter.

7.4.2.11 WKUP_R5FSS Boot Options

There are two methods of booting the R5F, or rather, two methods of placing the exception vectors (of which the boot vector is one).

The first method is to have the exception vectors external to the R5F. The user can place the exception vectors at the address indicated by the exception vector bootstrap and then program the boot vector there. When the processor exits reset, it will fetch the boot vector from this location.

The second method is to boot from a TCM. To do this, software should take the following steps:

1. Assert the correct bootstraps
   a. To boot from ATCM, set CPUn_INITRAMA (or CPUn_INITRAMB to boot from BTCM)
   b. Assert CPUn_LOCZRAMA properly for the desired TCM
2. Assert CPUn_HALT
3. Release the CPU from reset
4. Load the desired code into the TCM via the TCM target port
   a. Exception vectors should be located at address 0x00000000 of the TCM
5. De-assert CPUn_HALT

Copyright © 2026 Texas Instruments Incorporated

7.4.2.12 WKUP_R5FSS Core Memory ECC Events

The R5F core generates several events as part of event bus that can be monitored by the PMU for debugging. The memory ECC related events from the event bus are exported to ESM for monitoring.

There are two ECC interrupts to the ESM that aggregate different categories of ECC events – CPU single error, CPU multi error. Each ECC event has a 2-bit event bus counter associated with it. Everytime an event occurs, the counter is incremented by 1 till it reaches the max value of 3. The interrupt is asserted if the bus counter of any event associated with the interrupt is non-zero.

Each event bus counter has a MMR decrement control to decrement the counter by 1. So, for example, if a counter value is 2, the MMR to decrement the counter would need to be written 2 times to decrement the counter to 0. The reason decrement control has been added instead of clear control is if a new error occurs between the time the status register is read and the clear MMR is written, the new error would be lost. Write-to-decrement ensures that this does not happen.

When all event bus counters of an associated interrupt are zero, the interrupt is cleared. It takes three clock cycles for the event bus counter to be decremented once the write to the decrement control MMR presents itself at the WKUP_R5FSS boundary.

Since each of the four ECC interrupts have single bit control to set the interrupt but multiple bits for clearing it, note that once an interrupt is set using the R5FSS_EVNT_BUS_ESM_SET register, it can be cleared by setting all the bits of the R5FSS_EVNT_BUS_ESM_CLR register that correspond to that particular interrupt. For example, if bit [0] of the R5FSS_EVNT_BUS_ESM_SET register is set, it can be cleared by setting bits [7-0] of the R5FSS_EVNT_BUS_ESM_CLR register to clear the interrupt.

The R5F core event bus only signals event when it is enabled. Non-invasive or invasive debug mode needs to be enabled to enable the PMU counters.

The export of the events to the event bus can be enabled by setting the X bit in the Performance Monitor Control Register of the R5F core. For more details, refer to Arm R5 TRM.

Table 7-35. R5F Event Bus Single-Bit Error Events

Event Bus Bit #	Description	Associated Status Register

7.5 Vectored Interrupt Manager (VIM)

This section describes the VIM module in the device.

7.5.1 VIM Overview

The Vectored Interrupt Manager (VIM) aggregates interrupts to a CPU. It is intended for use with a Cortex R5 from ARM. The VIM has up to 1024 interrupt inputs, which may be either level or pulse. Each interrupt has a programmable priority (0-highestthrough 15-lowest). Each interrupt may also be mapped as an IRQ or FIQ (FIQ is also often denoted as Non-Maskable Interrupt, or NMI).

7.5.1.1 VIM Features

- 32-1024 Interrupt inputs
  - Configurable by groups of 32
- Each interrupt has its own 4-bit programmable priority
  - Supports Priority interruption of interrupts
- Each interrupt has its own enable mask
- Each interrupt can be programmed as either an IRQ or FIQ
- Each interrupt has its own programmable 32-bit Vector address associated with it
  - Protected with SECDED
- One IRQn and FIQn output
- Vectored Interrupt Interface
  - Compatible with ARM Cortex R5 VIC Port
- Default Vector provided when a Double-Bit error is detected
- Provides clock phase inputs so VIM can run at CPU clock while interface runs at a different, synchronous clock

7.5.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

Note

Some features may not be available. See *Module Integration* for more information.

7.5.2 VIM Functional Description

7.5.2.1 Block Diagram

Figure 7-19 shows the Vectored Interrupt Manager block diagram.

Copyright © 2026 Texas Instruments Incorporated

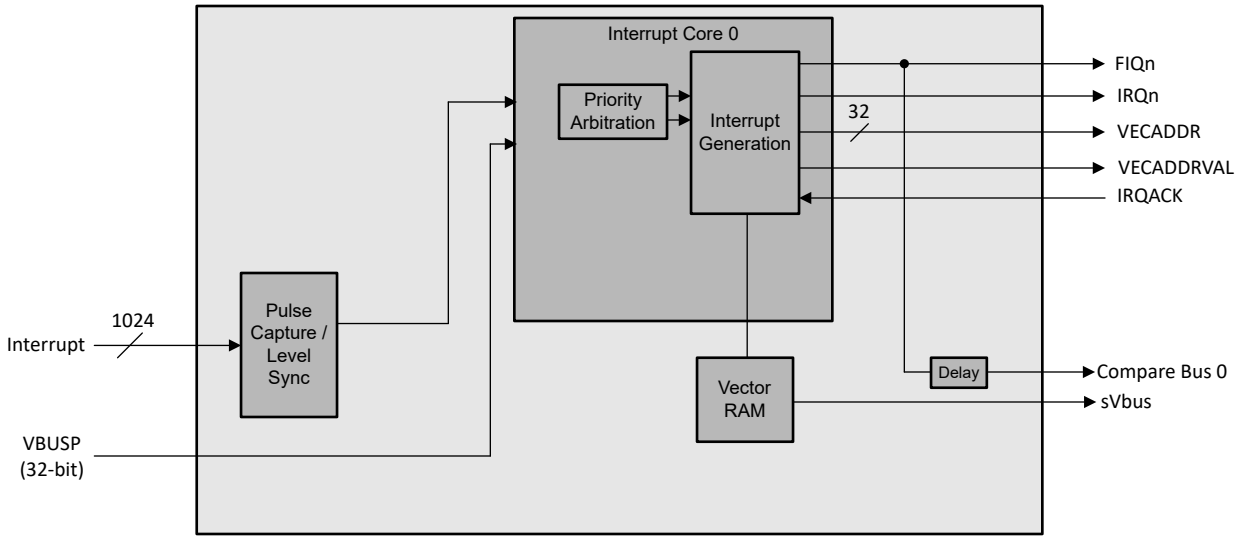

Figure 7-19. VIM Block Diagram

7.5.2.2 Interrupt Inputs

The VIM can have up to 1024 interrupt inputs, build-time configurable by multiples of 32 (*num_interrupts* parameter). Each interrupt can be either a level or a pulse (both active high).

Level interrupts are synchronized to the VIM clock. This synchronized value is captured in to a flop.

Pulse interrupts use rising edge detection. Each input has its own edge detection circuit. It is recommended that if pulses are pipelined between the source and the VIM, that the pipe stage replicates the pipe flop and ORs the output in order to protect against transient errors in the pipeline flop. Once an edge has been detected, the raw status is set.

There is no minimum pulse width, as true edge detection is used. The input signal should, however, be glitch free.

7.5.2.3 Interrupt Outputs

The VIM has two interrupt outputs, core*N*_IRQn and core*N*_FIQn (active low levels). Each interrupt input for core *N* can be programmed to influence either the core*N*_IRQn or core*N*_FIQn output via the Group *M* Interrupt Map Register (Base Address + 0x200 + *N**0x20 + 0x18).

7.5.2.4 Priority Interrupt / Nested Interrupts

Each interrupt has a priority number assigned to it (set using the 4.1.20 Interrupt *Q* Priority Register (Base Address + 0x1000 + *Q**0x4) register). Legal values are 0 to 15 where 0 is the highest priority and 15 is the lowest priority. The highest priority interrupt is the pending interrupt with the smallest priority number. If two pending interrupts have the same priority, the interrupt lowest numerically (0 through maximum number of interrupts) is prioritized. IRQs and FIQs are prioritized separately.

The VIM supports the interrupt of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate, but both use the same mechanism. When an interrupt goes from pending to active (FIQ: reading the FIQ Vector Address (Base Address + 0x1C), IRQ: reading the IRQ Vector Address (Base Address + 0x18) or the core*N*_IRQACK going high), then the interrupt is loaded into the corresponding Active Register, and all interrupts of an equal or lesser priority are masked off (see note below). If, before this interrupt is cleared (writing the FIQ Vector Address (Base Address + 0x1C) or IRQ Vector Address (Base Address + 0x18)) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. The CPU may or may not service the higher priority interrupt. If the CPU switches this interrupt to active, by reading the corresponding Vector Address Register (or core*N*_IRQACK going high for an IRQ) , then the currently active interrupt will be pushed on to a stack. When an interrupt is cleared by writing the Vector Address Register, if there are any interrupts on the stack, the first entry is popped off and put back into the Active

Copyright © 2026 Texas Instruments Incorporated

Register, so that software may continue where it left off. Note that the IRQVEC/FIQVEC address registers are *not* repopulated with the old vector as it's assumed that the ISR is picking back up where it left off. Only the interrupt number and priority are restored to the ACTIRQ/ACTFIQ registers. If software needs the vector again, it will have to read it by using the interrupt number.

Note

"Masked off" means that they are masked off from priority arbitration to interrupt the currently active interrupt, it does NOT mean that the status bits in the regsiters are masked off. That is, this priority masking has NO EFFECT on whether the status bits are visible in the masked registers such as the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04).

7.5.2.5 VIC Port

The VIM is designed to work with the VIC interface of an ARM Cortex R5.

7.5.2.6 Latency

There are several factors that go in to the speed of processing an interrupt: the interrupt controller, the processor, and the system latency.

The VIM behaves deterministically (except for synchronizer delay). Table 7-37 shows the latency of the VIM.

Table 7-37. VIM Latency

Step	Cycles	Note
Edge Detection	2-3	Synchronizing to VIM Clock
Interrupt Capture	1	
Prioritization and Vector Read	1	IRQ Could be stalled here if an FIQ is reading the Vector RAM
		IRQ/FIQ output asserted

The next factor is the processor itself

Table 7-38. Processor Interrupt Latency

Step	Cycles(1)	Note
Take Exception		
Store State		Stack system registers etc
Read Vector	1	Through MMR or VIC interface (for IRQ. VIC interface will be faster)
Jump to Vector		

(1) These steps are dependent on the processor. See R5 spec for details.

The final factor is system latency to access the actually instructions for the ISR. This will be dependent on where the instructions are (cache, TCM, system memory etc) and dependent on the system latency to reach those memories (1 cycle for cache/TCM, System dependent for external memory)

7.5.2.7 Safety

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the DED Vector Address (Base Address + 0x30) is used instead for the core*N*_IRQADDRV, IRQ Vector Address (Base Address + 0x18), and FIQ Vector Address (Base Address + 0x1C). The DED Vector Address should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling. Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
   a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device

Copyright © 2026 Texas Instruments Incorporated

4. Sit in a loop (or WFI) while something external (say the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

An interrupt that has an uncorrectable vector error and thus uses the DED Vector, will still have the priority of the original interrupt (that is for masking purposes). This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by an external ECC aggregator through sVbus ports.

7.5.2.8 IDLE

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface because it does not have a clock IPG. To clock stop the sub-system that includes the VIM, disable (mask) all interrupts and wait for the IDLE signal to assert.

7.5.3 Interrupt Conditions

7.5.3.1 CPU Interrupts

See Table 7-39 for the interrupts generated by the module.

Table 7-39. Interrupts

Interrupt	Description
core0_IRQn	IRQ Interrupt (Active Low)
core0_FIQn	FIQ Interrupt (Active Low)

7.5.3.2 Interrupt Description

7.5.3.2.1 coreN_IRQn

This is a normal interrupt, active low level, for Core N. It can be serviced via the VIC interface or through the MMR interface.

7.5.3.2.2 coreN_FIQn

This is a fast (or non-maskable) interrupt, active low level, for Core N. FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface.

7.5.3.3 Interrupt Condition Control

7.5.3.3.1 coreN_IRQn

Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (Group *N* Interrupt Map Register (Base Address + 0x200 + N*0x20 + 0x18)) and is enabled (Group *N* Interrupt Enabled Set Register (Base Address + 0x200 + N*0x20 + 0x08)), and its priority is not masked (4.1.11 IRQ Priority Mask Register (Base Address + 0x28), and it is not masked because of nested interrupt priority masking (2.2.5 Priority Interrupt / Nested Interrupts), then it will cause an IRQ to assert.

7.5.3.3.2 coreN_FIQn

Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ (Group *N* Interrupt Map Register (Base Address + 0x200 + N*0x20 + 0x18)) and is enabled (Group *N* Interrupt Enabled Set Register (Base Address + 0x200 + N*0x20 + 0x08)), and its priority is not masked (4.1.12 FIQ Priority Mask Register (Base Address + 0x2C)), and it is not masked because of nested interrupt priority masking (2.2.5 Priority Interrupt / Nested Interrupts), then it will cause an FIQ to assert.

7.5.3.4 Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM software wants to take advantage of. For IRQs, it is recommended to use 3.4.1 IRQ through the Vector

Copyright © 2026 Texas Instruments Incorporated

Interface, but 3.4.2 or 3.4.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives. For FIQs, it is recommended to use 3.4.4 FIQ, but 3.4.5 may be used as an alternative.

Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

7.5.3.4.1 IRQ through the Vector Interface

If the attached CPU has the Vector Interface enabled, then the following method is used for servicing IRQs

1. Hardware handshake
   a. CPU asserts coreN_IRQACK signal high
   b. VIM asserts coreN_IRQADDRV to indicate that the coreN_IRQADDR bus is stable with the correct Vector Address
   c. CPU reads the coreN_IRQADDR, jumps to that address, and de-asserts coreN_IRQACK signal low
   d. VIM de-asserts coreN_IRQn_intr and coreN_IRQADDRV, VIM masks all IRQs with the same or lower priority
   e. VIM loads the value from the Prioritized IRQ (Base Address + 0x08) (which corresponds to the vector address) to be loaded into the Active IRQ (Base Address + 0x20) and the valid bit to be set
2. Service an interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active IRQ (Base Address + 0x20) to determine number and reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group M Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group M Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
         2. If the source maintains the level, then it means there is another interrupt

4. 4. Write any value to the IRQ Vector Address (Base Address + 0x18)
   a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
   b. This will clear the valid bit of the Active IRQ (Base Address + 0x20)

7.5.3.4.2 IRQ through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the Vector Interface.

1. Read the IRQ Vector Address (Base Address + 0x18) and jump to that address to service the ISR

Copyright © 2026 Texas Instruments Incorporated

a. Reading this register will mask all interrupts of an equal or lower priority and de-assert the IRQn output. If another interrupt of a higher priority becomes available, the IRQn will re-assert, allowing priority interruption of an interrupt.
b. Reading this register will cause the value from the Prioritized IRQ (Base Address + 0x08) (which corresponds to the vector address) to be loaded into the Active IRQ (Base Address + 0x20) and the valid bit to be set

2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active IRQ (Base Address + 0x20) to determine number and reading the Group M Type Map Register (Base Address + 0x200 + M*0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
         2. If the source maintains the level, then it means there is another interrupt

4. Write any value to the IRQ Vector Address (Base Address + 0x18)
   a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
   b. This will clear the valid bit of the Active IRQ (Base Address + 0x20)

7.5.3.4.3 IRQ through MMR Interface (Alternative)

If a user does not want to use the Vector Address registers, the VIM may be used as a more traditional interrupt controller. Note that in this mode, priority masking will not work if route 1b is used (below) as the hardware prioritization may not match the software prioritization scheme. In this case, software would be responsible for doing all priority operations

1. Determine which interrupt to service
   a. Read the Prioritized IRQ (Base Address + 0x08) to determine which interrupt is the highest priority IRQ currently asserted OR
   b. Optionally read the IRQ Group Status (Base Address + 0x10) to determine which groups have IRQs pending, then read the Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10) and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Read the IRQ Vector Address (Base Address + 0x18)
   a. Note, this step can be done any time before step 4
   b. Value is ignored
4. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)

Copyright © 2026 Texas Instruments Incorporated

a. Pulse
   i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
   ii. Clear the interrupt at the source
      1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

b. Level
   i. Clear the interrupt at the source
   ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)
      1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
      2. If the source maintains the level, then it means there is another interrupt

5. Write any value to the IRQ Vector Address (Base Address + 0x18)

7.5.3.4.4 FIQ

When an FIQ interrupt is received, the CPU should follow these steps.

1. Read the FIQ Vector Address (Base Address + 0x1C) and jump to that address to service the ISR
   a. Reading this register will mask all interrupts of an equal or lower priority and de-assert the FIQn output. If another interrupt of a higher priority becomes available, the FIQn will re-assert, allowing priority interruption of an interrupt.
   b. Reading this register will cause the value from the Prioritized FIQ (Base Address + 0x0C) (which corresponds to the vector address) to be loaded into the Active FIQ (Base Address + 0x24) and the valid bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Active FIQ (Base Address + 0x24) to determine number and reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
         2. If the source maintains the level, then it means there is another interrupt

4. Write any value to the FIQ Vector Address (Base Address + 0x1C)

Copyright © 2026 Texas Instruments Incorporated

a. This will clear the priority mask and all interrupts to be re-evaluated for the new highest priority interrupt.
b. This will clear the valid bit of the Active FIQ (Base Address + 0x24)

7.5.3.4.5 FIQ (Alternative)

If a user does not want to use the Vector Address registers, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the FIQ Vector Address (Base Address + 0x1C) is never read). Software would be responsible for doing all priority operations

1. Determine which interrupt to service
   a. Read the Prioritized FIQ (Base Address + 0x0C) to determine which interrupt is the highest priority FIQ currently asserted OR
   b. Optionally read the FIQ Group Status (Base Address + 0x14) to determine which groups have IRQs pending, then read the Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14) and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (Determined by reading the Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C) to determine type)
   a. Pulse
      i. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
      ii. Clear the interrupt at the source
         1. This way, the source can generate another pulse if it needs to and the VIM will process this as a new interrupt

   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a 1 to the appropriate bit in the Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04) or Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)
         1. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt
         2. If the source maintains the level, then it means there is another interrupt

7.5.4 Memory Map

Each Interrupt Core (*N* = 0) has its own MMR interface with its own independent memory map

Table 7-40. Core *N* Memory Map

Address Offset	Register
0x00	Revision Register
0x04	Info Register
0x08	Prioritized IRQ
0x0C	Prioritized FIQ
0x10	IRQ Group Status
0x14	FIQ Group Status
0x18	IRQ Vector Address
0x1C	FIQ Vector Address
0x20	Active IRQ
0x24	Active FIQ

Table 7-40. Core *N* Memory Map (continued)

Address Offset	Register
0x28-0x2F	*Reserved*
0x30	DED Vector Address
0x34-0x1FF	*Reserved*
0x400 + *M**0x20 + 0x00	Group *M* Interrupt Raw Status/Set Register
0x400 + *M**0x20 + 0x04	Group *M* Interrupt Enabled Status/Clear Register
0x400 + *M**0x20 + 0x08	Group *M* Interrupt Enabled Set Register
0x400 + *M**0x20 + 0x0C	Group *M* Interrupt Enabled Clear Register
0x400 + *M**0x20 + 0x10	Group *M* Interrupt IRQ Enabled Status/Clear Register
0x400 + *M**0x20 + 0x14	Group *M* Interrupt FIQ Enabled Status/Clear Register
0x400 + *M**0x20 + 0x18	Group *M* Interrupt Map Register
0x400 + *M**0x20 + 0x1C	Group *M* Type Map Register
0x1000 + *Q**0x4 – 00x1FFF	Interrupt *Q* Priority Register
0x2000 + *Q**0x4 – 0x2FFF	Interrupt *Q* Vector Register

There are *M* interrupt groups (0 through *num_groups*-1) with 32 interrupts per group.

There are *Q* interrupt inputs where *Q* = *M* * 32.

Accesses to the Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q**0x4) must be word-aligned, 32-bit accesses. Any write received with no bytes enabled will be ignored. Any writes receive with all bytes enabled will be executed. Any other write will not execute and will return an error status of Addressing Error.

7.5.5 VIM Registers

7.5.5.1 Revision Register (Base Address + 0x00)

Table 7-41. Revision Register (Base Address + 0x00)

Bits	Field	Type	Reset	Description
31:30	scheme	r	01	Always read as 01. Writes have no effect.
29:28	bu	r	10	Always read as 10.
27:16	func	r	0x090	Always read as the assigned func id.
15:11	rtl	r	0x0	RTL version of the module. The “R” value in the X.Y.R.Z as defined by K3.
10:8	major	r	0x0	Major revision of module. The “X” value in the X.Y.R.Z defined in K3.
7:6	custom	r	0x0	Special version.
5:0	minor	r	0x1	Minor revision of module. The “Y” value in the X.Y.R.Z defined in K3

7.5.5.2 Info Register (Base Address + 0x04)

Table 7-42. Info Register (Base Address + 0x04)

Bits	Field	Type	Reset	Description
31:11	*reserved*	r/o	0	Always read as 0. Writes have no effect.
10:0	Interrupts	r/o	*num_groups* 32*	Indicates the number of interrupts supported by this VIM

Copyright © 2026 Texas Instruments Incorporated

7.5.5.3 Prioritized IRQ (Base Address + 0x08)

Table 7-43. Prioritized IRQ (Base Address + 0x08)

Bits	Field	Type	Reset	Description
31	valid	r/o	0	Indicates that the num field of this register is valid 1 – num field is valid (pending IRQ interrupt) 0 – num field is invalid (no pending IRQ interrupts)
30:20	*reserved*	r/o	0	Always read as 0. Writes have no effect.
19:16	pri	r/o	0	This field indicates the priority of the pending IRQ interrupt. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable
15:10	*reserved*	r/o	0	Always read as 0. Writes have no effect.
9:0	num	r/o	0	This field indicates the interrupt number of the pending IRQ interrupt with the highest priority. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable 0 – Interrupt 0 1 – Interrupt 1 1023 – Interrupt 1023 Note: The highest value is determined by the *num_groups* parameter

7.5.5.4 Prioritized FIQ (Base Address + 0x0C)

Table 7-44. Prioritized FIQ (Base Address + 0x0C)

Bits	Field	Type	Reset	Description
31	valid	r/o	0	Indicates that the num field of this register is valid 1 – num field is valid (pending FIQ interrupt) 0 – num field is invalid (no pending FIQ interrupts)
30:20	*reserved*	r/o	0	Always read as 0. Writes have no effect.
19:16	pri	r/o	0	This field indicates the priority of the pending FIQ interrupt. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable
15:10	*reserved*	r/o	0	Always read as 0. Writes have no effect.
9:0	num	r/o	0	This field indicates the interrupt number of the pending FIQ interrupt with the highest priority. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable 0 – Interrupt 0 1 – Interrupt 1 1023 – Interrupt 1023 Note: The highest value is determined by the *num_groups* parameter

7.5.5.5 IRQ Group Status (Base Address + 0x10)

Table 7-45. IRQ Group Status (Base Address + 0x10)

Bits	Field	Type	Reset	Description
31:0	*sts*	r/o	0	This field indicates that one or more interrupts in Group *M* are mapped to IRQ, unmasked, and pending. Bit 0 corresponds to Group 0; Bit 1 corresponds to Group 1 etc. The interrupts associated with each group are [(*M**32)+31:*M**32]

Copyright © 2026 Texas Instruments Incorporated

7.5.5.6 FIQ Group Status (Base Address + 0x14)

Table 7-46. FIQ Group Status (Base Address + 0x14)

Bits	Field	Type	Reset	Description
31:0	*sts*	r/o	0	This field indicates that one or more interrupts in Group *M* are mapped to FIQ, unmasked, and pending. Bit 0 corresponds to Group 0; Bit 1 corresponds to Group 1 etc. The interrupts associated with each group are [(*M**32)+31:*M**32]

7.5.5.7 IRQ Vector Address (Base Address + 0x18)

Table 7-47. IRQ Vector Address (Base Address + 0x18)

Bits	Field	Type	Reset	Description
31:2	addr	r/w	0x0	This field contains the upper 30 bits of the32-bit interrupt vector address (addresses must be 32-bit aligned) of the currently pending highest priority IRQ (as indicated by the num field of the Prioritized IRQ (Base Address + 0x08). This field is only valid if the valid flag in the Prioritized IRQ (Base Address + 0x08) register is set. • Reading this register returns the Interrupt Vector Address of the pending IRQ with the highest priority. It also has the following effects – Mask all IRQ interrupts of an equivalent or lower priority – De-asserts the IRQn signal – De-asserts the core*N*_IRQADDRV signal (if set) – Loads Active IRQ (Base Address + 0x20) • Writing any value to this register will not alter its contents, but will have the following effect – Remove the mask on all priorities
1:0	*reserved*	r/o	0x0	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

7.5.5.8 FIQ Vector Address (Base Address + 0x1C)

Table 7-48. FIQ Vector Address (Base Address + 0x1C)

Bits	Field	Type	Reset	Description
31:0	addr	r/w	0x0	This field contains the upper 30 bits of the 32-bit interrupt vector address (addresses must be 32-bit aligned) of the currently pending highest priority FIQ (as indicated by the num field of the Prioritized FIQ (Base Address + 0x0C). This field is only valid if the valid flag in the Prioritized FIQ (Base Address + 0x0C) register is set. • Reading this register returns the Interrupt Vector Address of the pending FIQ with the highest priority. It also has the following effects – Mask all FIQ interrupts of an equivalent or lower priority – De-asserts the FIQ n signal – Loads Active FIQ (Base Address + 0x24) • Writing any value to this register will not alter its contents, but will have the following effect – Remove the mask on all FIQ priorities
1:0	*reserved*	r/o	0x0	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

Copyright © 2026 Texas Instruments Incorporated

7.5.5.9 Active IRQ (Base Address + 0x20)

Table 7-49. Active IRQ (Base Address + 0x20)

Bits	Field	Type	Reset	Description
31	valid	r/o	0	Indicates that the num field of this register is valid. This field is set whenever the IRQ Vector Address (Base Address + 0x18) is read. It is cleared whenever the IRQ Vector Address (Base Address + 0x18) is written. 1 – num field is valid (active IRQ interrupt) 0 – num field is invalid (no active IRQ interrupts)
30:20	*reserved*	r/o	0	Always read as 0. Writes have no effect.
19:16	pri	r/o	0	This field indicates the priority of the active IRQ interrupt. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable
15:10	*reserved*	r/o	0	Always read as 0. Writes have no effect.
9:0	num	r/o	0	This field indicates the interrupt number of the active IRQ interrupt. This field is loaded with the value from the Prioritized IRQ (Base Address + 0x08) whenever the IRQ Vector Address (Base Address + 0x18) is read. This field is only valid if the valid flag (bit 8) is set. Otherwise the value is unpredictable 0 – Interrupt 0 1 – Interrupt 1 1023 – Interrupt 1023 Note: The highest value is determined by the *num_groups* parameter

7.5.5.10 Active FIQ (Base Address + 0x24)

Table 7-50. Active FIQ (Base Address + 0x24)

Bits	Field	Type	Reset	Description
31	valid	r/o	0	Indicates that the num field of this register is valid. This field is set whenever the FIQ Vector Address (Base Address + 0x1C) is read. It is cleared whenever the FIQ Vector Address (Base Address + 0x1C) is written. 1 – num field is valid (active FIQ interrupt) 0 – num field is invalid (no active FIQ interrupts)
30:20	*reserved*	r/o	0	Always read as 0. Writes have no effect.
19:16	pri	r/o	0	This field indicates the priority of the ACTIVE FIQ interrupt. This field is only valid if the valid flag (bit 31) is set. Otherwise the value is unpredictable
15:10	*reserved*	r/o	0	Always read as 0. Writes have no effect.
9:0	num	r/o	0	This field indicates the interrupt number of the active FIQ interrupt. This field is loaded with the value from the Prioritized FIQ (Base Address + 0x0C) whenever the FIQ Vector Address (Base Address + 0x1C) is read. This field is only valid if the valid flag (bit 8) is set. Otherwise the value is unpredictable 0 – Interrupt 0 1 – Interrupt 1 1023 – Interrupt 1023 Note: The highest value is determined by the *num_groups* parameter

7.5.5.11 IRQ Priority Mask Register (Base Address + 0x28)

Table 7-51. IRQ Priority Mask Register (Base Address + 0x28)

Bits	Field	Type	Reset	Description
31:16	*reserved*	r/o	0	Always read as 0. Writes have no effect.

Copyright © 2026 Texas Instruments Incorporated

Table 7-51. IRQ Priority Mask Register (Base Address + 0x28) (continued)

Bits	Field	Type	Reset	Description
15:0	*msk*	r/w	0xFFFF	This field is a bit vector to enable all IRQ interrupts of a given priority. Bit 0 corresponds to priority = 0 (highest) Bit 1 corresponds to priority = 1 etc.… 0 – IRQ of this priority are disabled 1 – IRQ of this priority are enabled

7.5.5.12 FIQ Priority Mask Register (Base Address + 0x2C)

Table 7-52. FIQ Priority Mask Register (Base Address + 0x2C)

Bits	Field	Type	Reset	Description
31:16	*reserved*	r/o	0	Always read as 0. Writes have no effect.
15:0	*msk*	r/w	0xFFFF	This field is a bit vector to enable all FIQ interrupts of a given priority. Bit 0 corresponds to priority = 0 (highest) Bit 1 corresponds to priority = 1 etc.… 0 – FIQ of this priority are disabled 1 – FIQ of this priority are enabled

7.5.5.13 DED Vector Address (Base Address + 0x30)

Table 7-53. DED Vector Address (Base Address + 0x30)

Bits	Field	Type	Reset	Description
31:2	addr	r/w	0x0	This field contains the upper 30 bits of the 32-bit interrupt vector address (the address must be 32-bit aligned) of an interrupt to be used if an uncorrectable double-bit error (DED) is detected in any of the interrupt vector addresses. If there is a DED, both the IRQ Vector Address (Base Address + 0x18) and FIQ Vector Address (Base Address + 0x1C) registers (along with the VECADDR output) will be populated with the value in this field instead of their normal vector. See section Section 7.3.3.2.4 , *Priority Interrupt / Nested Interrupts*. Safety on how to handle interrupts when there has been a DED • ECC Aggregator will indicate where there was a DED. Software may go correct that one location • Software may keep an ISR at the DED Vector which corrects the vectors or otherwise deals with the scenario • This mechanism is provided because there is no way to indicate on the coreN_IRQADDR to the CPU that the vector is invalid, and it is undesirable to have the CPU jump to a random address
1:0	*reserved*	r/o	0x0	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

7.5.5.14 Group *M* Interrupt Raw Status/Set Register (Base Address + 0x400 + *M**0x20 + 0x00)

Table 7-54. Group *M* Interrupt Raw Status/Set Register (Base Address + 0x400 + *M0x20 + 0x00)**

Bits	Field	Type	Reset	Description
31:0	sts	r/w1ts	0x0	This is the raw status of the events in Group *M*. Each bit corresponds to event *Q* where *Q* = *M**32+Bit (Example: bit 0 is event *M**32+0, bit 1 is *M**32 + 1 etc…) Read: 0 – Inactive 1 – Active/Pending Write: 0 – No effect 1 – Set to Interrupt Raw Status

7.5.5.15 Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x04)

Table 7-55. Group *M* Interrupt Enabled Status/Clear Register (Base Address + 0x400 + *M0x20 + 0x04)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w1tc	0x0	This is the masked status of the events in Group M. Each bit corresponds to event *Q* where *Q* = *M**32+Bit (Example: bit 0 is event *M**32+0, bit 1 is *M**32 + 1 etc…) Read: 0 – Inactive or Disabled 1 – Active/Pending and Enabled Write: 0 – No effect 1 – Clear Interrupt Raw Status

7.5.5.16 Group *M* Interrupt Enabled Set Register (Base Address + 0x400 + *M**0x20 + 0x08)

Table 7-56. Group *M* Interrupt Enabled Set Register (Base Address + 0x400 + *M0x20 + 0x08)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w1ts	0x0	This field is used to enable the mask of events in Group *M*. Each bit corresponds to event *Q* where *Q* = *M**32+Bit (Example: bit 0 is event *M**32+0, bit 1 is *M**32 + 1 etc…) Read: 0 – Disabled 1 – Enabled Write: 0 – No effect 1 – Set Enable

Copyright © 2026 Texas Instruments Incorporated

7.5.5.17 Group *M* Interrupt Enabled Clear Register (Base Address + 0x400 + *M**0x20 + 0x0C)

Table 7-57. Group *M* Interrupt Enabled Clear Register (Base Address + 0x400 + *M0x20 + 0x0C)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w1tc	0x0	This field is used to disable the mask of events in Group *M*. Each bit corresponds to event *Q* where *Q* = *M**32+Bit (Example: bit 0 is event *M**32+0, bit 1 is *M**32 + 1 etc…) Read: 0 – Disabled 1 – Enabled Write: 0 – No effect 1 – Clear Enable

7.5.5.18 Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x10)

Table 7-58. Group *M* Interrupt IRQ Enabled Status/Clear Register (Base Address + 0x400 + *M0x20 + 0x10)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w1tc	0x0	This is the masked status of the events in group *M* that are mapped to IRQ. Each bit corresponds to event *Q* where *Q* = *M**32+Bit (Example: bit 0 is event *M**32+0, bit 1 is *M**32 + 1 etc…) Read: 0 – Inactive, Disabled, or not an IRQ 1 – Active/Pending, Enabled, and IRQ Write: 0 – No effect 1 – Clear Interrupt Raw Status (if IRQ)

7.5.5.19 Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M**0x20 + 0x14)

Table 7-59. Group *M* Interrupt FIQ Enabled Status/Clear Register (Base Address + 0x400 + *M0x20 + 0x14)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w1tc	0x0	This is the masked status of the events in group *M* that are mapped to FIQ. Each bit corresponds to event *Q* where *Q* = *M**32+Bit (Example: bit 0 is event *M**32+0, bit 1 is *M**32 + 1 etc…) Read: 0 – Inactive, Disabled, or not an FIQ 1 – Active/Pending, Enabled, and FIQ Write: 0 – No effect 1 – Clear Interrupt Raw Status (if FIQ)

Copyright © 2026 Texas Instruments Incorporated

7.5.5.20 Group *M* Interrupt Map Register (Base Address + 0x400 + *M**0x20 + 0x18)

Table 7-60. Group *M* Interrupt Map Register (Base Address + 0x400 + *M0x20 + 0x18)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w	0x0	This field is used to indicate which interrupt the corresponding event influences (if enabled) for event group *M*. Each bit corresponds to event *Q* where *Q* = *M**32+Bit (Example: bit 0 is event *M**32+0, bit 1 is *M**32 + 1 etc…) 0 – IRQ Interrupt (default) 1 – FIQ Interrupt

7.5.5.21 Group *M* Type Map Register (Base Address + 0x400 + *M**0x20 + 0x1C)

Table 7-61. Group *M* Type Map Register (Base Address + 0x400 + *M0x20 + 0x1C)**

Bits	Field	Type	Reset	Description
31:0	msk	r/w	0x0	This field is used to indicate whether the source of an interrupt is a level (default) or a pulse for event group *M*. This is informational so that an ISR may query this register and know whether it has to clear a pulse event or a level event *(see Section 7.3.3.3.4 Interrupt Handling)*. The value has no effect on how the VIM hardware functions. The input interrupts are agnostic as to whether they are pulse or level. Each bit corresponds to event *Q* where *Q* = *M**32+Bit (Example: bit 0 is event *M**32+0, bit 1 is *M**32 + 1 etc…) 0 – Level (default) 1 – Pulse

7.5.5.22 Interrupt *Q* Priority Register (Base Address + 0x1000 + *Q**0x4)

Table 7-62. Interrupt *Q* Priority Register (Base Address + 0x1000 + *Q0x4)**

Bits	Field	Type	Reset	Description
31:4	*reserved*	r/o	0	Always read as 0. Writes have no effect.
3:0	pri	r/w	0xF	This is the priority for interrupt *Q*. If two interrupts have the same priority, then whichever interrupt has the lower number *Q* wins arbitration 0 – Highest Priority 1 …. 14 15 – Lowest Priority (Default)

Copyright © 2026 Texas Instruments Incorporated

7.5.5.23 Interrupt Q Vector Register (Base Address + 0x2000 + Q*0x4)

Table 7-63. Interrupt Q Vector Register (Base Address + 0x2000 + Q*0x4)

Bits	Field	Type	Reset	Description
31:2	addr	r/w		This is the 32-bit Vector Address associated with interrupt *Q*. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt *Q* is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1:0	*reserved*	r/o	0x0	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

7.5.6 Module I/O

7.5.6.1 Clocks, Reset, Emulation

Table 7-64. Clocks, Reset, Emulation

Pin Name	Type	Function
core0_clk	In	Clock for Core 0
core0_phase	In	Phase Indicator for Core 0
core0_srst_n	In	Sync Module Reset for Core 0
core0_arst_n	In	Async Module Reset for Core 0
core0_clkstop_idle	Out	Clock Stop Idle

7.5.6.2 VBUSP Target Interface

(N=0). Core0 interface is used for interrupt core 0.

Table 7-65. VBUSP Target Interface

Pin Name	Type	Function
core*N*_cfg_req	In	Request
core*N*_cfg_address[13:0]	In	Address (byte address)
core*N*_cfg_dir	In	Direction (read or write)
core*N*_cfg_xcnt[2:0]	In	Transaction Count
core*N*_cfg_byten[3:0]	In	Byte enables
core*N*_cfg_wdata[31:0]	In	Write data
core*N*_cfg_rdatap[31:0]	Out	Read data
core*N*_cfg_rready	Out	Read ready
core*N*_cfg_wready	Out	Write ready
core*N*_cfg_rstatus[2:0]	Out	Read Status
core*N*_cfg_emudbg	In	Emulation Debug

7.5.6.3 Interrupt Inputs

Core0 interface is used for interrupt core 0.

Table 7-66. Interrupt Inputs

Pin Name	Type	Function
core0_in_intr[*Q*-1:0]	In	Core 0 Interrupt Inputs

7.5.6.4 Interrupt Outputs

Table 7-67. Interrupt Outputs

Pin Name	Type	Function
core0_IRQn_intr	Out	IRQ Interrupt for core 0– Active Low Level
core0_FIQn_intr	Out	FIQ Interrupt for core 0 – Active Low Level

7.5.6.5 VIC Interfaces

(*N*=0). Core0 interface is used for interrupt core 0.

Table 7-68. VIC Interfaces

Pin Name	Type	Function
core*N*_vic_IRQADDRV	Out	IRQ Address Valid
core*N*_vic_IRQADDR[31:2]	Out	IRQ Address
core*N*_vic_IRQACK	In	Interrupt Acknowledge

7.5.6.6 Compare Outputs

These pins will never be on an isolation boundary and therefore their isolation values are don't-care. *Y* is dependent on the configuration

Table 7-69. Compare Outputs

Pin Name	Type	Function
core0_compare_bus[*Y*:0]	Out	Comparison Bus for Core0 to CCMR5

7.5.6.7 ECC Control and Status Bus

(*N*=0). Core0 interface is used for interrupts for core 0.

Table 7-70. ECC Control and Status Bus

Signal Name	Dir	Default Val	Description
core*N*_ramecc_strb	In	1'b0	Strobe to sample the incoming serial data
core*N*_ramecc_txd	In	1'b0	Output serial data
core*N*_ramecc_rxd	Out	1'b0	Input serial data
core*N*_ramecc_pend[1:0]	Out	2'd0	Level Interrupt source

7.5.6.8 DFT

Table 7-71. DFT

Signal Name	Dir	Default Val	Description
dft_clk_force_en	In	1'b0	DFT Clock Force Enable
dft_partition_enn	In	1'b0	DFT Clock Partition Enable
dft_scan_en	In	1'b0	DFT Scan Enable
dft_async_rst_sel	In	1’b0	DFT Async Reset Select
dft_test_async_rst_n	In	1’b0	DFT Async Test Reset
dft_tft_mcp_dis	In	1’b0	DFT MCP Disable

Table 7-71. DFT (continued)

Signal Name	Dir	Default Val	Description
dft_local_clk_en	In	1'b0	DFT Local Clock Enable

7.5.6.9 RAM GPIO

Table 7-72. RAM GPIO

Signal Name	Dir	Default Val	Description
core*N*_ramdft_gpi[255:0]	In	256'd0	RAM GPI
core*N*_ramdft_gpo[255:0]	Out	256'd0	RAM GPO

7.5.7 Programmer's Guide

7.5.7.1 Initialization Sequence

At initialization, the following tasks should be performed:

1. Program the DED Vector Address (Base Address + 0x30)
2. Program Group *M* Interrupt Map Register (Base Address + 0x200 + *M**0x20 + 0x18)
3. Program Group *M* Type Map Register (Base Address + 0x200 + *M**0x20 + 0x1C)
4. Program Interrupt *Q* Priority Register (Base Address + 0x1000 + *Q**0x4)
5. Program Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q**0x4)
6. Enable interrupts via the Group *M* Interrupt Enabled Set Register (Base Address + 0x400 + *M**0x20 + 0x08)

Note that the Interrupt *Q* Vector Register (Base Address + 0x2000 + *Q**0x4) for each interrupt that will be enabled must be written before the interrupt is enabled, even if software is not going to use the vector. Whenever an interrupt is prioritized, the RAM location for the interrupt is read, and if that location is un-initialized, an ECC error will be reported. If the vectors aren't being used, then the RAM can be initialized by writing 0x0 to every location.

7.5.7.2 DED Behavior

Whenever there is 2-bit error detect on a Vector Address, the DED Vector Address (Base Address + 0x30) overrides all other vectors. Software should provide an ISR to handle this scenario at this address.

7.5.7.3 Power Up/Down Sequence

Before a clean power down, software should check that there are no pending interrupts, disable all interrupts, and wait for the clkstop_idle output.

7.6 Video Encoder/Decoder (VENC/VDEC)

The following sections describe the video accelerator details for the device.

7.6.1 Introduction

The Video Accelerator is a 4K codec that supports both HEVC and H.264/AVC video formats. It provides high performance encode and decode capability up to 8bit 4K@60fps with a single-core architecture.

The Video Accelerator can encode and/or decode any resolution up to 8192 x 4320. It guarantees real-time performance for encoding/decoding 4K 60fps based on its sophisticated, latency tolerant hardware architecture. The Video Accelerator is highly optimized for memory bandwidth loading and excellent power management.

The Video Accelerator contains a 32-bit processor called V-CPU, which is responsible for parsing bitstream syntax in decoder orencoding bitstream syntax in encoder from sequence to slice header unit, pre-scanning slice data, controlling the underlying video hardware blocks called V-CORE. The V-CPU also communicates with host CPU through host register interface. The V-CORE performs actual processing of coded slice data: entropy decoding, inverse scan, inverse transform/quantization, motion compensation, and loop filtering in decoder and motion estimation, intra prediction, RDO, and entropy coding in encoder. This software and hardware combined architecture can provide flexibility and high throughput at the same time.

7.6.2 Features

7.6.2.1 Performance

H.265/HEVC Encoder

- Capable of encoding HEVC Main and Main Still Picture Profile @ L5.1 High tier
  - Maximum resolution: 8192x8192
    - The maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
  - Minimum resolution: 256x128
  - Constraints
    - A picture width shall be multiple of 8.
    - A picture height shall be multiple of 8.

Table 7-73. HEVC Encoder Performance

PicWidth	PicHeight	MHz/60fps 160Mbps
3840	2160	500

H.264/AVC Encoder

- Capable of encoding Baseline/Constrained Baseline/Main/High Profiles Level @ L5.2
  - Maximum resolution: 8192x8192
    - The maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
  - Minimum resolution: 256x128
  - Constraints
    - A picture width shall be multiple of 8.
    - A picture height shall be multiple of 8.

Table 7-74. H.264/AVC Encoder Performance

PicWidth	PicHeight	MHz/60fps 72Mbps
3840	2160	500

H.265/HEVC Decoder

- Capable of decoding HEVC Main and Main Still Picture Profile @ L5.1 High tier
  - Maximum resolution: 8192x4320
    - The Maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
  - Minimum resolution: 8x8

Table 7-75. H.265/HEVC Decoder Performance

PicWidth	PicHeight	MHz/60fps 160Mbps
3840	2160	450.00

H.264/AVC Decoder

- Capable of decoding Baseline/Constrained Baseline/Main/High Profiles @ L5.2
  - Maximum resolution: 8192x4320
    - The Maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
  - Minimum resolution: 32x32

7.6.2.2 Codec Related Features

H.265/HEVC Encoder

- Fully compatible with ISO/IEC 23008-2 high efficiency video coding main profile
- I/P slices
- CTU64
  - Supportable prediction unit (PU) size: 32 x 32, 16 x 16, 8 x 8
  - Supportable transform unit (TU) size: 32 x 32 to 4 x 4
- Parallel tools
  - Wavefront parallel processing (WPP) encoding with a single slice
  - Multi slice: Independent slice segment and dependent slice segment
- High performance offline CABAC encoding
- Motion estimation
  - 1/4-pel precision motion vectors
  - Search range [+/-128H, +/-64V] with an adaptive search center
  - Two reference frames for P-slice
  - Long-term reference for P picture
- Custom tuning tools
  - Custom Lambda map and lambda table
  - Custom mode decision
  - Fully programmable user scaling list
- In-loop filter
  - Deblocking filter
  - Sample adaptive offset (SAO)
  - Loop filtering across slices
- Strong intra smoothing on/off
- Transform skip
- Lossless coding
- Picture/CTU/subCTU level of rate control
- Region of interest (ROI) encoding with custom QP map
- 3DNR
- Adaptive intra refresh (AIR) for error resilience

H.264/AVC Encoder

- Compatible with the ITU-T recommendation H.264 specification. All coding tools in the baseline, con- strained baseline, main, and high profiles are supported.
  - With a few exceptions:
    - Interlaced coding tools are not supported.
    - FMO/ASO tool of H.264 is not supported.
- 16 x 16, 8 x 8 and 4 x 4 block sizes are supported and configurable.
- Motion estimation
  - 1/4-pel accuracy motion estimation with programmable search range up to [+/-64, +/-48]
  - One reference frame for P-slice
- Intra prediction
  - Luma I4 x 4 Mode: 9 modes
  - Luma I8 x 8 Mode: 9 modes
  - Luma I16 x 16 Mode: 4 modes (vertical, horizon, DC, plane)
  - Chroma mode: 3 modes (vertical, horizon, DC)
- Custom tuning tools

Copyright © 2026 Texas Instruments Incorporated

  - User-defined mode (skip, intra) map
  - User-defined QP map
  - Lambda tuning for custom mode decision
  - Fully programmable user scaling list
- In-loop deblocking filter
- CABAC/CAVLC support
- Error resilience tools:
  - Cyclic intra refresh (CIR)
  - Multi-slice structure
- A frame level and MB level of rate control
- Region of interest (ROI) encoding with custom QP map

H.265/HEVC decoder

- Fully compatible with ISO/IEC 23008-2 high efficiency video coding main/MSP (main still picture) profile. All coding tools in the profile are supported.
- I/P/B slices
  - All intra-prediction modes
  - All inter-prediction modes
- Variable CTU size: 64 x 64 to 16 x 16
  - Variable prediction unit (PU) size: 64 x 64 to 4 x 4
  - Variable transform unit (TU) size: 32 x 32 to 4 x 4
- Advanced motion vector prediction (AMVP) and merge mode
- A quarter motion compensation with 8 tap filters
- Uniform reconstruction quantization (URQ)
- Parallel coding tools
  - Multi tile
  - Wavefront parallel processing (WPP)-encoded bitstream support
  - Multi slice: Independent slice segment and dependent slice segment
- High performance CABAC decoding
- In-loop deblocking filtering
- Sample adaptive offset (SAO)
- Loop filtering across slice/tile boundaries
- Data reporting to the external host
- Robust error concealment
- Sequence change detection

H.264/AVC Decoder

- Fully compatible with the ITU-T recommendation H.264 specification. All coding tools in the baseline/constrained baseline/main/high profile are supported.
  - With a few exceptions:
    - Interlaced coding tools are not supported.
    - FMO/ASO tool of H.264 is not supported.
- Variable block size (16 x 16, 16 x 8, 8 x 16, 8 x 8, 8 x 4, 4 x 8 and 4 x 4)
- CABAC/CAVLC support
- In-loop deblocking filter
- Error detection, concealment and error resilience tools

7.6.2.3 Non-Codec Related Features

Rotation and mirroring

The Video Accelerator supports 8 modes of rotation and mirroring. The PRP block can do rotations of the source picture in 90, 180, or 270 degrees and vertical or horizontal flip before starting to encode the operation.

Bit-depth and chroma format conversion

Copyright © 2026 Texas Instruments Incorporated

The PRP block is responsible for source format conversion in the encoder IP. 422 (planar/semi-planar) to 420 conversion can be made before encoding operation.

Frame buffer compression

To overcome bandwidth suffering and at the same time to ensure real-time encode/decode performance, TI has carefully designed lossless, great access patterned frame buffer compression technology and employed it into the WAVE IP series. WAVE521CL achieves significant reduction in bandwidth while sustaining fast processing capability.

Long Burst Write

The Video Accelerator includes burst write back (BWB) module that enables 128-byte burst write access to external memory for better bus utilization. It collects a group of short write requests from loop filter block in 128-byte unit and sends it out to the external memory more efficiently. BWB works for an external Display module or other post processing module that needs to read decoded frames in raster scan order.

The FBC/FBD block also writes or reads 128-byte burst length of compressed frame data from/to the externalmemory.

3DNR

The Video Accelerator employs temporal noise reduction technology, also called 3DNR (3D noise reduction), for better quality of image under low light. Video noise appears easily in a low light level. It is an important issue in surveillance camera because images are captured often under dark conditions or indoors, which can make identification difficult.

The Video Accelerator can detect and filter noise for each color component Y, Cb, and Cr of a frame. This achieves both good video quality and enhancement of coding efficiency. Noise reduction is done while encoding. Therefore, additional read/write bandwidth is not required.

Note

3DNR is supported in the H.265/HEVC encoder only.

Latency tolerance

The Video Accelerator can afford to reach real time performance under memory access latency if the number of cycles per CTU retains less than 500 cycles. The Video Accelerator is designed to be less sensitive to pipeline delay, especially at a peak bitrate, which might eventually incur performance drop. With use of decoupling techniques and inter-pipe queues, it can hide this sort of delay and deliver high performance at any situation.

Subframe synchronization

The Video Accelerator supports subframe synchronization for low latency coding. By receiving dedicated subframe-ready signals from the image process unit (IPU) or by setting host interface registers from host CPU, the Video Accelerator can start encoding process as early as the minimum set of raw video data is ready.

Programmability

The Video Accelerator embeds the 32-bit CPU and 16-bit DSP dedicated to bitstream processing and their video hardware control. Host interface registers and interrupts are provided for communication between a host processor and the Video Accelerator.

Low Power Consumption

The Video Accelerator can ensure ultra-low power operation by gating the clock sources for some internal hardware blocks in an idle state.

Trick mode

The Video Accelerator supports trick mode such as fast/slow forward playback and fast/slow reverse playback for video applications. By seeking an intra random access point (IRAP) picture as entry points of bitstream, the

Copyright © 2026 Texas Instruments Incorporated

Video Accelerator can skip non-IRAP pictures and start decoding from an IRAP picture or decode a thumbnail of a picture.

Frame-based processing

V-CPU processor operates video operation on a frame by frame basis. While frame operation is running, there is no need for communication between the host processor and the Video Accelerator. This is the key feature for promising the lowest burden to host processor for video operations.

By issuing a picture processing, the host application can perform its own operations until it receives an interrupt from the Video Accelerator informing of the completion of picture processing.

Handling multi-instances

The Video Accelerator supports multiple instances, which can be helpful for multi-channel encoder and/or decoder applications. To support this multi-instance operation, the Video Accelerator uses an internal context parameter set for each instance. While creating a new instance and starting picture processing, a set of these context parameters is created and updated automatically in the Video Accelerator. Because of this internal context management scheme, different encoder and/or decoder tasks running on the host processor can control Video Accelerator operations independently with their own instances.

When creating a new instance, an application task will get a new handle specifying an instance if a new handle is available on the Video Accelerator. All of the following operations for the given application task could be separately handled on the Video Accelerator by using this task-specific handle. Because the Video Accelerator can only perform one picture processing task at a time, each application task should check whether the Video Accelerator is ready or not before starting a new picture operation. By calling a function for closing a certain instance, the application can easily terminate a single task of video operation on the Video Accelerator.

7.6.3 Block Diagram

Figure 7-20 shows the hierarchical architecture of the Video Accelerator and external bus interfaces.

Copyright © 2026 Texas Instruments Incorporated

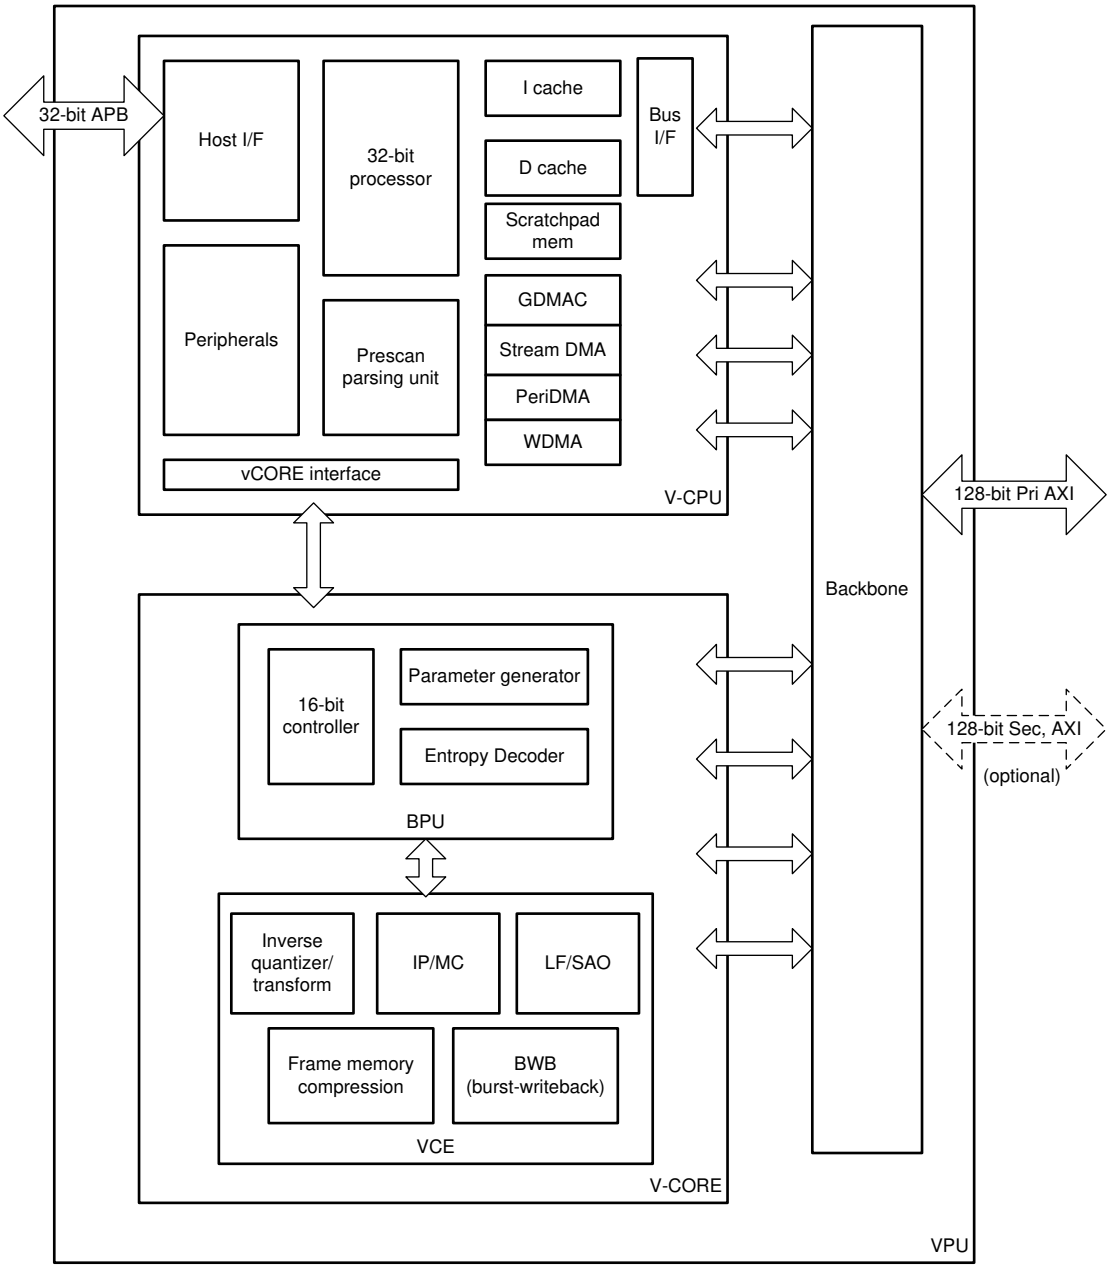

Figure 7-20. Video Accelerator Block Diagram

The Video Accelerator is built on a layer structure for efficient video processing. It is composed of two main parts, V-CPU and V-CORE. V-CPU is a 32-bit processor where the Video Accelerator L1 driver software is running. It mainly encodes and decodes a high-level syntax of bitstream - SPS/PPS/SH, and communicates with the host processor, such as receiving a picture level command from the host processor or sending the result of video task through the 32-bit AMBA3 APB bus. V-CPU can also parse necessary parameters and give necessary slice/tile-level information to the underlying V-CORE hardware.

Particularly in case of an HEVC decoder, V-CPU uses a virtual wavefront parallel processing (VWPP) scheme to balance processing load among V-COREs and to simplify its operation. During the VWPP, V-CPU parses bitstream and extracts some data from bitstream such as CABAC context, QP, and start address for each row and tile. After that, V-CPU reorders the data to meet the WPP processing sequence and dispatches them to the appropriate V-COREs.

Copyright © 2026 Texas Instruments Incorporated

V-CORE can encode and decode a slice unit of data. It consists of a 16-bit DSP called a bit processor unit (BPU) and a group of video codec hardware blocks called a video codec engine (VCE).

- BPU is responsible for packing and parsing of coded slice data, CTU/CU/PU/TU-level parameter derivation, and finally passing slice data over to the VCE. To speed up entropy encoding/decoding, some hardware accelerators are included in the BPU.
- On the other hand, VCE is an actual hardware core executing a series of decoding process - encoding and decoding process - motion estimation, intra-prediction, RDO, and entropy coding with their hardwired logics, motion compensation, inverse-transformation/quantization, and loop filter with their hardwired logics. HEVC and H.264/AVC decoders share most of the internal VCE memories and full logics in certain VCE blocks like intra-prediction for small gate count.

They are doing these tasks with CTU-based pipelines and FIFO queues to ensure real-time speed and performance. When it comes to system connection as shown in the Figure 7-20, there is one 32-bit AMBA3 APB interface connecting to the host processor, and there are two 128-bit AMBA3 AXI bus interfaces connecting to the external memory controller for reading and writing picture data and temporal data.

- Primary AXI: AXI interface to read or write work data and coded picture (bitstream), decoded picture data and so forth.
- Secondary AXI (optional): On-chip-SRAM connected AXI interface to read or write temporal buffer required for V-CORE operation. This is an optional interface that can be used to alleviate bandwidth usage.

7.7 Vision Pre-processing Accelerator (VPAC)

This chapter describes the Vision Pre-processing Accelerator (VPAC) in the device.

7.7.1 VPAC Overview

The Vision Pre-processing Accelerator (VPAC) subsystem is a set of common vision primitive functions, performing pixel data processing tasks, such as: color processing and enhancement, noise filtering, wide dynamic range (WDR) processing, lens distortion correction, pixel remap for de-warping, on-the-fly scale generation, on-the-fly pyramid generation. The VPAC offloads these common tasks from the main SoC processors (ARM, DSP, etc.), so these CPUs can be utilized for differentiated high-lelvel algorithms. The VPAC is designed to support multiple cameras by working in time-multiplexing mode. The VPAC also includes an imaging pipe, which can be integrated on-the-fly with external camera sensor, as well as does memory-to-memory (M2M) processing on pixel data.

Figure 7-21 provides an overview of the VPAC subsystem.

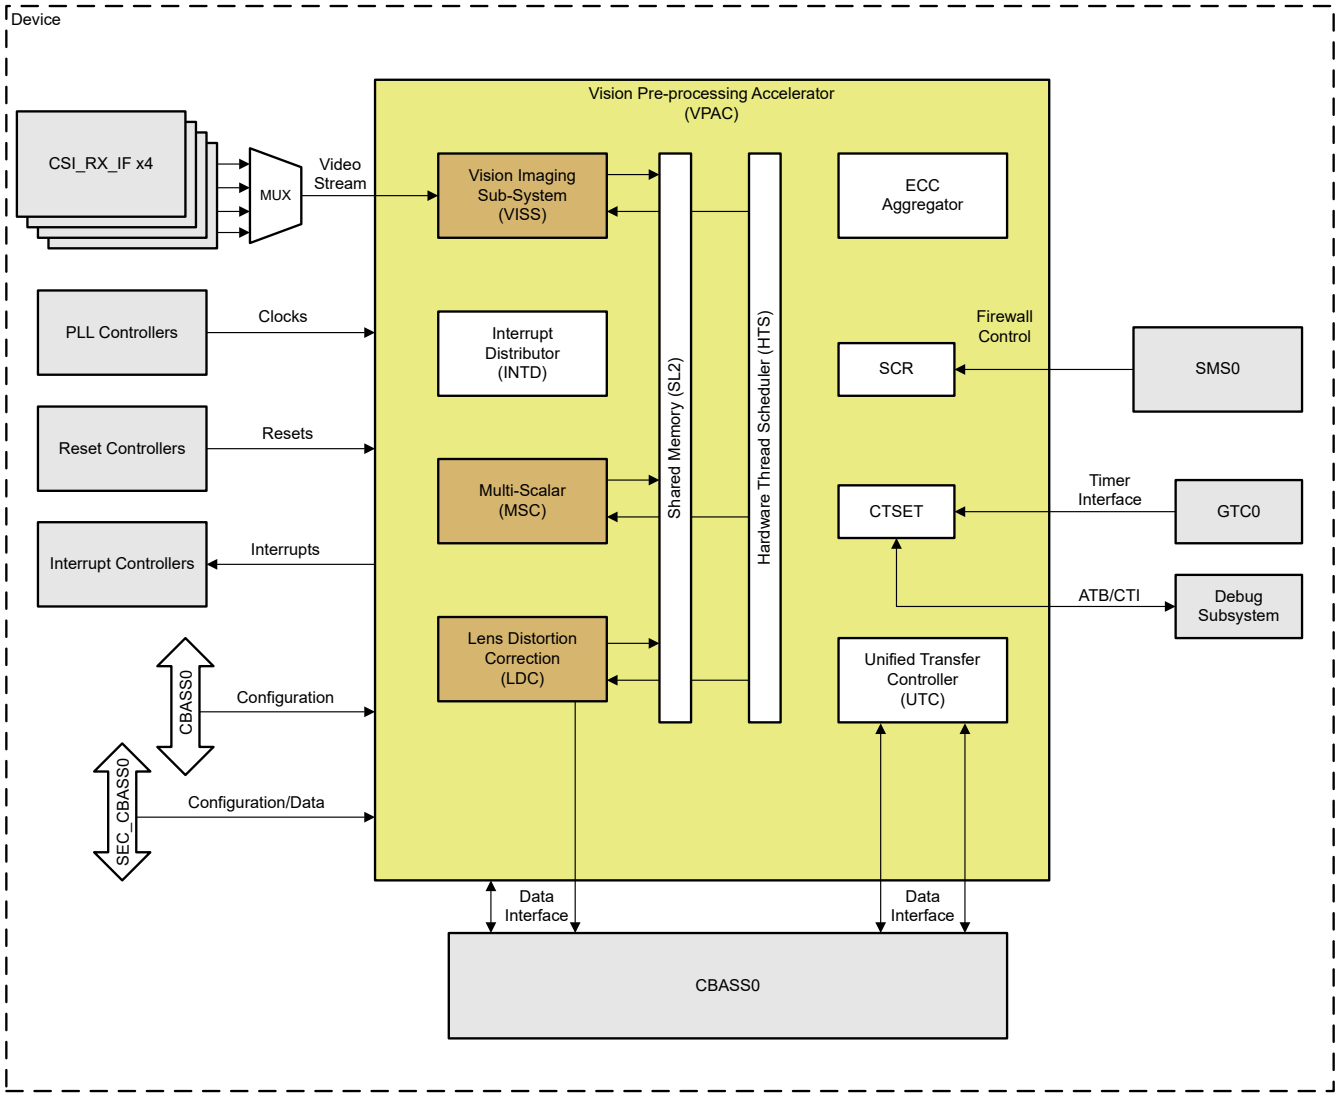

Figure 7-21. VPAC Overview

7.7.1.1 VPAC Features

The VPAC includes the following processing and infrastructure sub-modules:

Copyright © 2026 Texas Instruments Incorporated

- Vision Imaging Sub-System (VISS). The vision imaging pipe does image processing on raw data which includes Wide Dynamic Range (WDR) merge, Defect Pixel Correction (DPC), Lens Shading Correction (LSC), Global/Local Brightness and Contrast Enhancement (GLBCE), Spatial Noise Filtering, demosaicing, color conversion, and Edge Enhancement (EE). It can operate on sensor data either on-the-fly or in memory-to-memory mode. The VISS provides the following main features:
  - Performance is up to 1 pixel/cycle
  - Up to 16-bit input RAW formats (8b, 12b, 14b, 16b) (see Section 7.7.2.7)
    - Support for generic 2x2 RAW format (Bayer, RCCB, RCCC, etc.)
    - Support for 4x4 RGB-IR RAW format
  - Processing up to 4096 pixels/line (8MP frame)
  - Support for concurrent 12-bit and 8-bit YUV output
  - Support for other color spaces:
    - RGB output
    - Support for color saturation and gray scale for HSV/HSL, etc.
  - Support for multiple WDR/HDR formats (for 2x2 RAW formats):
    - Combined Companded format (up to 16-bit companded)
    - Separated Exposures – up to 3 frame Motion Adaptive HDR Merge
    - Staggered HDR
    - Digital Lateral Overlap (DLO)
  - Support of statistics for Auto-Exposure/Auto-White-Balance or Auto-Focus (configurable option to select either AE/AWB or AF)
  - Support for Flexible CFA for generating multi-plane output for any 2x2 RAW format sensor configuration.
    - Supports RCBC, RCCC, Bayer, RGBC as well as other formats
    - Can generate up to 4 independent color planes
    - Support for up two 3 directions per color plane
    - Adaptive threshold based on intensity measure
  - Supports pattern conversion (remosaicing RGB-IR(4x4) CFA format raw data into 2x2 Bayer pattern) and IR demosaicing
  - Support for multiple color format output generation
    - Supports traditional 12-bit YUV output
    - Support for 8-bit YUV output) (see Section 7.7.2.7)
    - Supports RGB output (8-bit only)
    - Supports saturation outputs (8 bits only)
    - Supports Grayscale/Luma/IR/Clear output
  - Global/Local Brightness and Contrast Enhancement module (16-bit)
  - Spatial Noise Filter (NSF4V)
    - Supports raw input image in generic 2x2 color pattern format including Bayer pattern
    - Supports 16-bit raw input image
    - Spatially adaptive noise level threshold
    - Configurable soft or hard thresholding
    - Supports elliptical lens shading gain adjustment of adaptive noise threshold with 2 sets of independent settings
    - White Balance gain
    - Signal level detection with flexible cross-color-channel or independent averaging
  - Option to bypass visual enhancement functions (NSF4V and GLBCE)
  - Edge Enhancement (EE)
    - Enhance the visual quality of the image (Luma only)
    - Edge enhancer filter and the edge sharpener filter can be combined by configuration
    - Option to bypass visual enhancement functions (CAC, NSF4V, and GLBCE)
- Lens Distortion Correction (LDC) block. The LDC engine is YUV domain processor designed to perform perspective and geometric transforms. This can be used for creating several effects, including but not limited to:
  - Lens Distortion Correction, including Fish Eye Lenses

Copyright © 2026 Texas Instruments Incorporated

  - Epipolar rectification for Stereo
  - Generic perspective transforms for rotation scaling or Augmented Reality like effects

  The output of the LDC block can be sent to external memory (DDR) or sent to other VPAC sub-module (MSC) for further pre-processing via local shared memory (SL2). The LDC block provides the following main features:

  - Performance up to 1 cycle/pixel (bilinear) and 2 cycles/pixel (bicubic)
  - Autonomous memory-to-memory operation
  - Tile based processing
  - Generic mesh based distortion model to correct multiple distortion types
  - Perspective warp transformation for perspective correction; affine transform is a subset of perspective warp and supports scaling and rotation
  - Supported formats (see Section 7.7.2.7):
    - YUV420 12-bit packet input and YUV420 12-bit packed output
    - YUV420 12-bit unpacked input and YUV420 12-bit unpacked output
    - YUV420 8-bit packet input and YUV420 8-bit packed output
    - YUV422 8-bit packed input and YUV420 8-bit packed output
    - YUV422 8-bit packed input and YUV422 8-bit packed output
  - Supports up to 8192 x 8192 image dimension
  - Pixel Interpolation
    - Bicubic interpolation for Y and bilinear interpolation for Cb/Cr
    - Bilinear interpolation mode to offer double throughput
  - Support of Luma Only or Chroma Only Mode
  - Supports variable block size frame processing (9 regions)
- Multi-Scalar (MSC) block. The MSC block reads data from memory (DDR or on-chip) to shared memory (SL2) and generates up to 10 scaled outputs from a given input with varios scaling ratios (between 1x and x0.25). The output of the MSC block can be sent to external memory (DDR) from the local shared memory (SL2). The MSC supports two independent threads (scalars), which combined can generate up to max 10 scales. The MSC block provides the following main features:
  - Multi-scaling capable: 10 simultaneous scaled outputs from 1 or 2 input planes; up to 2 simultaneous processing thread with total of 10 scaled output with 1 to N and 1 to M configurations (where N+M <=10)
  - Each scaling engine can be configured to perform Pyramid or inter-octave scale generation
  - Scaling ratio supported: 1x ~ x/4 (with 1x scaling, MSC can perform a 3~5-tap generic separable convolution filtering)
  - 5-tap separable filter kernel implementation
  - Programmable kernel sizes for vertical/horizontal filter (3, 4, or 5)
  - Poly phase implementation with support of 64 or 32 phases poly phase support
  - 4 sets of 5-tap x 32 phase coefficients (two can be combined to support 5-tap x 64 phase coefficients and one of set can hold additional 5-tap customer filter coefficients for non-resizing filter)
  - 2 additional sets of 5-tap Gaussian filter coefficients (single-phase) dedicated for Pyramid (Octave) generation
  - Coefficients in 10-bit (S10Q8 format - signed value of 10 bits with 8-bit fraction)
  - Separate initial horizontal and vertical phase programming option
  - Support for two planes of data processing
    - Data in a plane can be uniform (for example, Y plane) or interleaved (Cb/Cr interleaved)
  - 8-bit or 12-bit component data
  - Performance up to 1 input pixel/cycle
  - Output data rate is dependent on downscaling ratio
  - Programmable input and output ROI (or clipping) for each scaler
  - On-the-fly (OTF) or memory-to-memory (M2M) operation with line buffers in SL2 (frame resolution support is not constrained by MSC line buffer)
- Hardware Thread Scheduler (HTS). The HTS block used for inter-processor communication among various VPAC sub-modules (VISS, LDC, MSC) and with the local DMA Engine (UTC). The HTS block provides the following main features:

Copyright © 2026 Texas Instruments Incorporated

  - Scheduling the HWA threads and associated tasks
  - Enables rate-controlled task execution
  - Support running several independent threads asynchronously in the sub-system
  - Debug functions:
    - Halting HWA threads at logical task boundary
    - Handling pipeline suspend and subsequent abort by software intervention
- Shared Level 2 (SL2) memory. The SL2 is used as intermediate storage for Hardware Accelerator (HWA) to exchange data across VPAC sub-modules (that is, VISS, LDC, MSC) and from DDR/System Memory. VPAC supports Realtime and Non-Realtime processing threads simultaneously.

Copyright © 2026 Texas Instruments Incorporated

7.7.2 VPAC Subsystem Level

This section covers VPAC subsystem-level details.

7.7.2.1 VPAC Subsystem Block Diagram

The VPAC subsystem includes imaging pipe to do image processing on raw pixels (bayer, RCCC, etc.). The VPAC subsystem loads pixel data either from memory (for example, DDR or on-chip memory), or captured from camera sensor (via external module on SoC level), and applies many vision primitive functions such as image processing, scaling to generate image pyramids, noise filtering, correcting lens distortion, applying perspective transformation for stereo rectification, etc. Optionally, the VPAC subsystem can also do dynamic range management on received image data. The output image processed data generated by the VPAC subsystem is written into memory (for example, DDR or on-chip). The VPAC subsystem supports software managed and HTS controlled flexible load/store of data using K3 DMA infrastructure sub-modules.

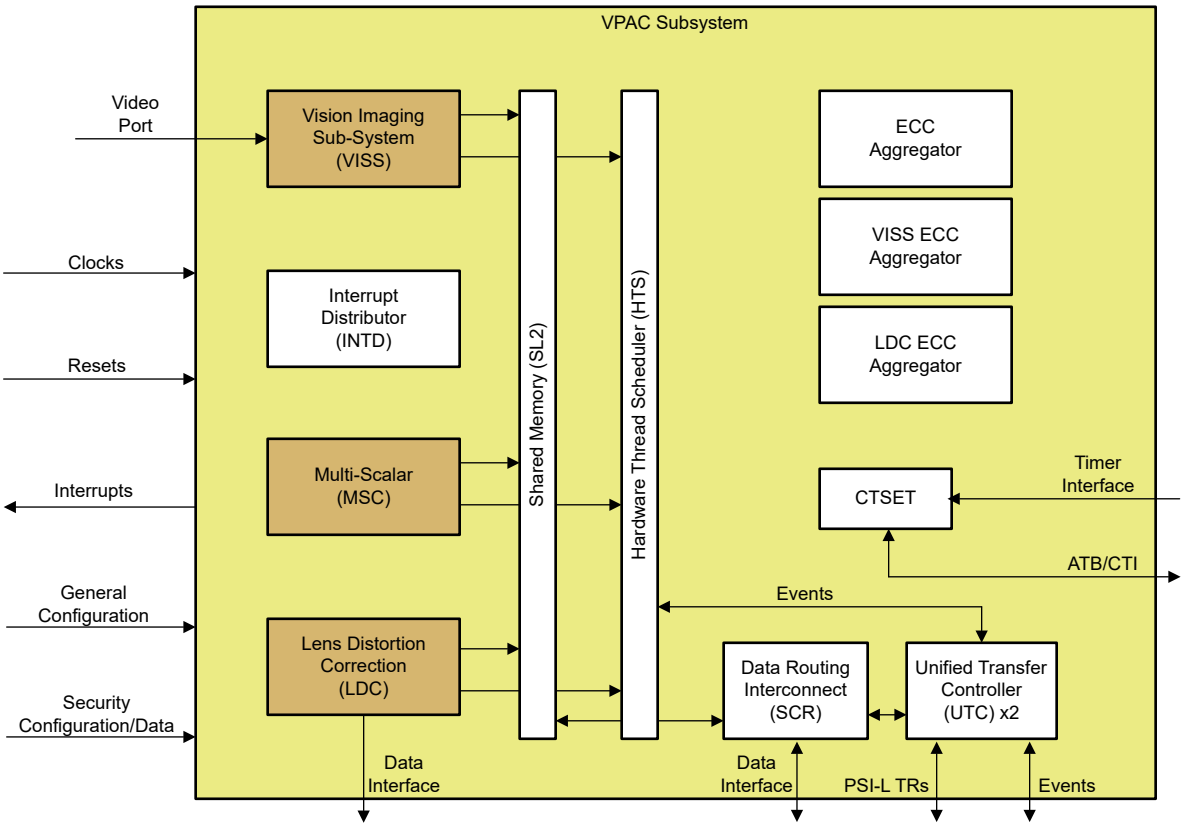

Figure 7-22. VPAC Subsystem Block Diagram

The VPAC subsystem includes the following image processing harware accelerators (HWAs) and infrastructure blocks:

- Vision Imaging Subsystem (VISS). The VISS does on-the-fly (OTF) processing on raw pixels captured from camera sensor. It also does memory to memory processing for data captured from other sources to its parallel port or video port. The VISS uses VPAC infrastructure modules (HTS, DRU/UTC, interrupt aggregator, etc.) for flow and data management. For more information on the VISS operation and the sub-modules integrated inside, see Section *VPAC Vision Imaging Subsystem (VISS)*. The VISS consists of following Hardware Accelerators (HWA):
  - RAW Front End (RFE) block: The RFE block does RAW pixel (that is, Bayer, RCCC, RGBW, 4x4 RGBIR, etc.) processing on captured image data from sensor. The processed data is later passed on to the NSF4V block, or otherwise it is passed onto the Flexible Color Proccesing (FCP) block for demosaicing and color conversion. In case of the 4x4 RGBIR image data passed on to Pattern Conversion and IR Demosaicing (PCID) before being processed by the downstream blocks. The RFE includes also the H3A

Copyright © 2026 Texas Instruments Incorporated

block, which supports the control loops for auto focus (AF), auto white balance (AWB) and auto exposure (AE) by computing image statistics.
  - Pattern Conversion and IR Demosaicing (PCID) module: The PCID module is used only to process the 4x4 RGB-IR CFA pattern RAW data to up-sample/demosaic IR channel to full resolution and re-mosaic the input pattern to create 2x2 Bayer CFA pattern data to be processed by existing VISS blocks. The PCID module can also be used to decontaminate the 2x2 Bayer CFA pattern data of IR contamination. The PCID module can further remap the demosaiced IR channel image to compress the dynamic range. Further the 2x2 Bayer CFA pattern generated by the PCID block can be looped back to the H3A block within RAWFE to collect AE/AWB statistics.
  - Global Local Brightness Contrast Enhancement (GLBCE) module: The GLBCE module is used for dynamic range control within image for visual quality. If a contrast enhancement on the input image is required for visual quality, the RFE output is processed by the NSF4v and GLBCE blocks and then passed onto the FCP block. Otherwise, if contrast enhancement is not required, the NSF4v and GLBCE blocks can be bypassed, and the RFE output is directly provided to the FCP block.
  - Flexible Color Processing (FCP) block: The FCP block receives data from GLBCE and does demosaicing and color conversion. The output of the color processing is sent to the internal EE (Edge Enhancer) block, if it is enabled, before being ouput to VPAC shared memory. Otherwise, the FCP output data is directly sent to VPAC shared memory to be written into external memory for further vision processing by programmable processors (that is, DSP or Arm), or other vision hardware accelerators at SoC level.
  - Load/Store Engine (LSE): The LSE is an infrastructure block, which provides the following functions:
    - Receives data, captured through MIPI CSI-2 image sensor (by external module at SoC level), for on-the-fly image processing to reduce DDR bandwidth and latency. LSE also provides horizontal and vertical blanking cycles to allow core data path to settle at proper boundary of line and frame.
    - Provides access to VPAC SL2 memory for loading/storing data. Loaded data from SL2 are passed on to unpacker function of LSE for RFE. Packed data after FCP/H3A processing is written into SL2.
    - Event control. HTS events are generated at line level. These events are routed to RFE to start the processing. For each consumed line HTS needs *task done* indication. For some initial lines consumed, there would not be any valid data output. Similarly, H3A generated data will be at paxel/window height number of lines.
- Lens Distortion Correction (LDC) module. The LDC module deals with lens geometric distortion issues in the camera system. The distortion can be common optical distortions, such as barrel distortion, pin-cushion distortion, or fisheye distortion. Correction is not limited to just these types of distortions. The LDC module consists of a Back Mapping block (which gives coordinates of the distorted image as a function of coordinates of the undistorted output image), a delta_x/delta_y offset table, frame buffer inetrface, buffer, an interpolation block, and SL2 interface. The frame buffer is external to the LDC module, and is usually in an off-chip SDRAM. The LDC module uses the common VPAC infratructure modules (HTS, DRU/UTC, interrupt aggregator, etc.) for flow and data management, except for loading input data for which it has its own DMA engine. For more details on the LDC operation, see Section *VPAC Lens Distortion Correction (LDC)*.
- Multi-Scaler (MSC) module. The MSC consists of 10 programmable resizers performing multi-thread/multi-scaling operations (2-input to N-outputs, and 2-input to M-outputs, where N+M is 10 or less). Each processing thread of MSC reads its input plane data from the SL2 circular line buffer, performs multi-scaling operations (ratios between X and 0.25X) on the same input, and writes out results to SL2 circular line buffers. In case of on-the-fly operation, the source data is generated from another VPAC HWA. In case of memory-to-memory operation, the source data is read from the external memory. Data transfers from/to SL2 to/from external memory (or another HWA) are handled by the VPAC DMA controller (DRU/UTC), with transfer request events coming from the VPAC HTS module. The MSC module uses the VPAC infrastrucutre modules (HTS, DRU/UTC, interrupt aggregator, etc.) for flow and data management. For more details on the the MSC operation, see Section *VPAC Subsystem Multi-Scaler (MSC)*.
- Hardware Thread Scheduler (HTS). The HTS module is a messaging layer for low-overhead synchronization of the parallel computing tasks and DMA transfers, and is independent from the host processor. It allows autonomous frame level processing for the VPAC subsystem. The HTS module defines various aspects of synchronization and data sharing between the VPAC HWAs. With regards to producer and consumer dependencies, the HTS module ensures that a task starts only when input data and adequate space to write out data is available. In addition to this, it also takes care of pipe-up, debug, abort and interrupt management

Copyright © 2026 Texas Instruments Incorporated

aspects related to the VPAC HWAs. For more details on the HTS operation, see Section *VPAC Hardware Thread Scheduler (HTS)*.
- Common shared level 2 (SL2) memory. The SL2 memory subsystem implements a full crossbar inteconnect, and serves as input/output scratch memory for the VPAC HWAs.
- Unified Transfer Controller (UTC): UTC is a VPAC DMA engine to handle real-time and nonreal-time data transfers.
- Data Routing Unit. The SCR acts like a 256-bit data routing interconnect within the VPAC subsystem, and is used to route UTC traffic onto SL2 memory or for external (system level) access.
- Counter, Timer and System Event Trace (CTSET) module. The CTSET module provides event tracing capabilities for debug purposes.
- ECC Aggregator. The ECC Aggregator modules provide a mechanism to control and monitor certain internal ECC RAMs via Single Error Correction (SEC) and Double Error Detection (DED) functions.

7.7.2.1.1 Notes on VISS RFE H3A Usage

The H3A module supports the control loops for auto focus (AF), auto white balance (AWB) and auto exposure (AE) by computing image statistics. The statistics are typically used by the host CPU to adjust the various parameters for processing the image data. The H3A module comprises two sub modules: the AF and AE/AWB. The H3A module, which is integrated inside RFE module of VISS, can be configured to produce either AE/AWB or AF statistics in a sigle run. Data generated is stored into a separate SL2 memory buffer by writes of 32-Byte data in a single burst. There is support of only one H3A output channel between LSE and HTS.

The H3A output data is a single dimensional data and the amount of data produced depends on number of windows/paxel in a frame, varions functional modes and corner cases of multiple of 8 windows/paxels in a row, finishing row level statistics at 32-Byte boundary, etc. Table 7-77 shows the size of data produced, depending on H3A configuration.

Table 7-77. VPAC Subsystem H3A Output Data Size

Register Settings		Number of Bytes	Special care
AF H3A_PCR[0] AF_EN = ‘1’	Vertical AF disabled H3A_PCR[20] AF_VF_EN = ‘0’	48 Bytes/paxel	If paxel_no_x odd, add 16B per row to make it 32B multiple per row.
	Vertical AF enabled H3A_PCR[20] AF_VF_EN = ‘1’	64 Bytes/paxel	None
AE and AWB H3A_PCR[16] AEW_EN = ‘1’	Sum of square H3A_AEW_CFG[9-8] AEFMT = ‘0’	34 Bytes/window	(+16B) After 8 windows (+16B) At end of row, but no end of windows, if H3A size at Row != 32B (+16B) Num of windows %8 !=0 (+16B) At end of windows, if H3A size at end of windows != 32B
	Min/Max H3A_AEW_CFG[9-8] AEFMT = ‘1’	34 Bytes/window	
	Sum only H3A_AEW_CFG[9-8] AEFMT = ‘2’	18 Bytes/window	

The parameters of H3A output buffer need to be configured via VISS LSE register settings. Some special considerations include:
- Configure the H3A line size to be more or equal to maximum H3A data produced in a row. That is, VISS_LSE_BUF_ATTR[15-6] H3A_LN_SIZE >= ceil((# of output bytes per H3A paxel/window row)/64)
- The H3A output data is 1-dimensional in the external storage (DDR or on-chip memory). For ease of synchronization, this 1-D data is converted into multiple of H3A line data. The TR (transfer request) written to transfer H3A data from SL2 to external storage must make sure to configure offset such that data get stored as if 1-D continuous data.
- Configure the minimum VISS LSE_BUF_ATTR[24-16] CBUF_SIZE = 3, to take care of corner cases.

7.7.2.2 VPAC Subsystem Clocks

Each block within the VPAC subsystem receives its own clocking signal:

Copyright © 2026 Texas Instruments Incorporated

- MAIN_CLK is the operation clock for all infrastructure modules, such as UTC/DRU, HTS, ECC Aggregator, INTD, etc.
- VISS0_CLK is the operation clock for the VISS and its sub-modules
- LDC0_CLK is the operation clock for the LDC module
- MSC_CLK is the operation clock for the MSC module

For more details on the source of each clock at SoC level, see *VPAC Integration*.

7.7.2.3 VPAC Subsystem Resets

Each block within the VPAC subsystem can be reset through its own HW reset signal:

- MAIN_RST is the reset for all infrastructure modules, such as UTC/DRU, HTS, ECC Aggregator, etc.
- VISS0_RST is the reset for the VISS and its sub-modules
- LDC0_RST is the reset for the LDC module
- MSC_RST is the reset for the MSC module

For more details on the source of each reset signal at SoC level, see *VPAC Integration*.

7.7.2.4 VPAC Subsystem Interrupts

The VPAC subsystem outputs six physical system interrupt lines: VPAC_LEVEL_0_INTR through VPAC_LEVEL_5_INTR. For more information on how the interrupt lines are connected at SoC level, see *VPAC Integration*. The interrupt aggregation within the VPAC subsystem is done using the internal INTD module. Each interrupt line can be mapped to the same list of source interrupt events generated by the modules within the VPAC subsystem.

Table 7-78 shows the INTD interrupt control registers for each VPAC interrupt line. Each interrupt line has a separate set of registers for level and pulse input event types. Each bit in a register corresponds to a particular interrupt event.

- The ENABLE registers enable the mapping of the internal VPAC interrupt events, generated by a module within the VPAC subsystem, to the VPAC output system interrupt lines. Writing a '1' in a register bit position allows the corresponding module interrupt event to trigger the respective system interrupt. Writing a '0' in the same bit position blocks the module interrupt event from triggering the system interrupt.
- The ENABLE_CLR registers disables the mapping of the internal VPAC interrupt events to the VPAC output system interrupt lines.
- The STATUS registers are used to capture which VPAC sub-module interrupt events, that have been mapped to a system interrupt, are active and pending. This status is used when multiple module interrupts are grouped into a single system interrupt, so the software can read the status register to determine exactly which module interrupt has caused the system interrupt.
  - For level interrupts, the status is based on the active level of the module interrupt input, and when the input is inactive then the status is inactive as well.
  - For pulsed interrupts, the status is set upon the pulse and reflects a pending status and software must clear the pending status since the module does not indicate the inactive status (unlike a level interrupt, which does).
- The STATUS_CLR registers allows software to clear the pending status of interrupt events. This register is only valid and functional for pulsed interrupts and has no effect for level interrupts.

The VISS interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_0 through VPAC_INTD_xxx_VPAC_OUT_5_0 registers. Table 7-79 provides more details on the VISS interrupt events. All VISS interrupts are single pulse event signals.

Table 7-79. VPAC Subsystem VISS Interrupt Events

Register Bit	Interrupt Event Name	Description
0	RAWFE_CFG_ERR_INTR	Config read or write memory acccess occurred during functional operation and likely corrupted functional opertion. VISS merges all config error sources from RawFE and see section *RAWFE Interrupts* for the entire error source list. h3a_line_cfg_err_intr and h3a_accm_cfg_err_intr sources can be generated errornously on access outside of active frame window to H3A Line and Accumalator memories respectvely if none of the H3A functions are enable in previous frame.
1	RAWFE_AEW_PULSE_INTR	H3A AEW interrupt.
2	RAWFE_AF_PULSE_INTR	H3A AF interrupt.
3	RAWFE_H3A_PULSE_INTR	H3A interrupt.
4	RAWFE_H3A_BUF_OVRFLOW_PULSE_INTR	H3A output buffer overflow.
5	NSF4V_LINEMEM_CFG_ERR_INTR	VBUSP diagnostic read access of RAM, while NSF data using RAM for functional purpose.
6	NSF4V_HBLANK_ERR_INTR	Horizontal Blanking too short between lines.
7	NSF4V_VBLANK_ERR_INTR	Vertical Blanking too short between frames.
8	GLBCE_CFG_ERR_INTR	Either non-shadowed registers written or statastic memories are accessed during active window.
9	GLBCE_FILT_START_INTR	GLBCE started filtering. This interrupt is issued at the rising edge of filtering signal.
10	GLBCE_FILT_DONE_INTR	GLBCE ended filtering. This interrupt is issued at the falling edge of filtering signal.
11	GLBCE_HSYNC_ERR_INTR	Generated when delayed HS/HE signals doesn't match with derived signals from GLBCE core.

Copyright © 2026 Texas Instruments Incorporated

Table 7-79. VPAC Subsystem VISS Interrupt Events (continued)

Register Bit	Interrupt Event Name	Description
12	GLBCE_VSYNC_ERR_INTR	Generated when delayed VS/VE signals doesn't match with derived signals from GLBCE core.
13	GLBCE_VP_ERR_INTR	This interrupt is issued, if there is a data input while filtering is high.
14	FCFA_CFG_ERR_INTR	Either non-shadowed registers written or line memories are accessed during active window.
15	FCC_CFG_ERR_INTR	Configuration access to registers/memories has corrupted functional operation.
		Configuration read or write memory acccess occurred during functional operation.
		Merged independent error sources at VISS. Refer to Section *VISS Flexible Color Processing (FCP)* for all sources.
16	FCC_OUTIF_OVF_ERR_INTR	FIFO overflow on FIFO for Y12 LSE I/F. Merged all FCC output overflow error sources at VISS. Refer to Section *VISS Flexible Color Processing (FCP)* for all sources.
17	FCC_HIST_READ_ERR_INTR	Host was not able to read the entire histogram mem between VS-VE window (triggered when the first access to histogram has been performed but the last has not been performed). Error won't be reported if Histogram Read starts in Vertical Blanking. Instead use the SW sequence suggested in the spec to read the FCC histogram
18	EE_CFG_ERR	Cinfiguration happened to EE regions causing corruption during frame processing.
19	EE_SYNCOVF_ERR	EE horizontal synchronization FIFO overflow interrupt.
20	LSE_FR_DONE_EVT_INTR	LSE frame done interrupt.
21	LSE_SL2_RD_ERR_INTR	Set whenever there is an error response on VBUSM read command for any input channel.
22	LSE_SL2_WR_ERR_INTR	Set whenever there is an error response on VBUSM write command for any output channel.
23	LSE_CAL_VP_ERR_INTR	Set whenever one of the following input frame errors is detected at VPORT_INPUT.
24	LSE_OUT_FR_START_EVT_INTR	Ouput Frame Start (from VISS top level).
25	RAWFE_X_Y_POINTER_INTR	X,Y pixel position has reached the start of RAWFE pipeline interrupt.
26	VISS_CR_CFG_ERR_INTR	Config read/write access happened to CAC MeshLUT or PCIR IR RemapLUT when CAC or PCID data is active (active window - IN_VS to OUT_VE).
27	RAWFE_DPC_STATS_READ_ERR_INTR	Host was not able to read the entire DPC corrected location memory VS-VE window (Triggered when the first access to statastics memory has been performed but the last has not been performed)

The LDC interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_1 through VPAC_INTD_xxx_VPAC_OUT_5_1 registers. Table 7-80 provides more details on the LDC interrupt events. All LDC interrupts are single pulse event signals.

Table 7-80. VPAC Subsystem LDC Interrupt Events

Register Bit	Interrupt Event Name	Description
0	LDC_PIX_IBLK_OUTOFBOUND_INTR	Back mapped pixel co-ordinate goes out of the pre-computed input pixel bounding box.
1	LDC_MESH_IBLK_OUTOFBOUND_INTR	Block mesh co-ordinate goes out of the pre-computed mesh bounding box.
2	LDC_PIX_IBLK_MEMOVF_INTR	Input Pixel block memory overflow.
3	LDC_MESH_IBLK_MEMOVF_INTR	Mesh block memory overflow.
4	LDC_IFR_OUTOFBOUND_INTR	Back mapped input co-ordinate goes out of input frame range.
5	LDC_INT_SZOVF_INTR	Affine and perspective transform precision overflow error.
6	LDC_FR_DONE_EVT_INTR	Frame done LDC.
7	LDC_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.
8	LDC_VBUSM_RD_ERR_INTR	Error on Input VBUSM Read interface.

Copyright © 2026 Texas Instruments Incorporated

The MSC interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_2 through VPAC_INTD_xxx_VPAC_OUT_5_2 registers. Table 7-81 provides more details on the MSC interrupt events. All MSC interrupts are single pulse event signals.

Table 7-81. VPAC Subsystem MSC Interrupt Events

Register Bit	Interrupt Event Name	Description
0	MSC_LSE_FR_DONE_EVT_0_INTR	Frame done MSC processing thread 0.
1	MSC_LSE_FR_DONE_EVT_1_INTR	Frame done MSC processing thread 1.
2	MSC_LSE_SL2_RD_ERR_INTR	Error on SL2 VBSUM Read interface.
3	MSC_LSE_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.

The HTS interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_3 through VPAC_INTD_xxx_VPAC_OUT_5_3 registers. Table 7-82 provides more details on the HTS interrupt events. All HTS interrupts are single pulse event signals, save for the SPARE_PEND_xxx interrupts, which can be both single pulse events and level events.

Table 7-82. VPAC Subsystem HTS Interrupt Events

Register Bit	Interrupt Event Name	Description
0	PIPE_DONE_0	Pipeline 0 done.
1	PIPE_DONE_1	Pipeline 1 done.
2	PIPE_DONE_2	Pipeline 2 done.
3	PIPE_DONE_3	Pipeline 3 done.
4	PIPE_DONE_4	Pipeline 4 done.
5	PIPE_DONE_5	Pipeline 5 done.
6	PIPE_DONE_6	Pipeline 6 done.

9	TDONE	HWA2 thread done.
10	RESERVED	Reserved.
11	TDONE	HWA4 thread done.
12	TDONE	HWA5 thread done.
13	TDONE	HWA6 thread done.
14	SPARE_DEC_0	Spare 0 scheduler decrement pulse (ehost mode).
15	SPARE_DEC_1	Spare 1 scheduler decrement pulse (ehost mode).
16	SPARE_PEND_0_PULSE	Spare 0 scheduler pend assertion (ehost mode).
17	SPARE_PEND_0_LEVEL	Spare 0 scheduler pend assertion (ehost mode).
18	SPARE_PEND_1_PULSE	Spare 1 scheduler pend assertion (ehost mode).
19	SPARE_PEND_1_LEVEL	Spare 1 scheduler pend assertion (ehost mode).
20	WATCHDOGTIMER_ERR_0	Watchdog Timeout Error for HWA0.
21	RESERVED	Reserved.
22	WATCHDOGTIMER_ERR_2	Watchdog Timeout Error for HWA2.
23	RESERVED	Reserved.
24	WATCHDOGTIMER_ERR_4	Watchdog Timeout Error for HWA4.
25	WATCHDOGTIMER_ERR_5	Watchdog Timeout Error for HWA5.
26	WATCHDOGTIMER_ERR_6	Watchdog Timeout Error for HWA6.

The UTC interrupt events indicating TR complete are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_4 through VPAC_INTD_xxx_VPAC_OUT_5_4 registers for UTC0, and VPAC_INTD_xxx_VPAC_OUT_0_5 through VPAC_INTD_xxx_VPAC_OUT_5_5 plus

Copyright © 2026 Texas Instruments Incorporated

VPAC_INTD_xxx_VPAC_OUT_0_6 through VPAC_INTD_xxx_VPAC_OUT_5_6 registers for UTC1. Table 7-83 provides more details on the UTC TR complete interrupt events. All UTC TR complete interrupts are single pulse event signals.

Table 7-83. VPAC Subsystem UTC TR Complete Interrupt Events

Register Bit	Interrupt Event Name	Description
31-0	UTC0_COMPLETE_INTR[31:0]	TR complete interrupt.
31-0 plus 31-0	RESERVED	Reserved.

The UTC interrupt events indicating error are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_7 through VPAC_INTD_xxx_VPAC_OUT_5_7 registers for both UTC0 and UTC1. Table 7-84 provides more details on the UTC error interrupt events. All UTC error interrupts are single pulse event signals.

Table 7-84. VPAC Subsystem UTC Error Interrupt Events

Register Bit	Interrupt Event Name	Description
0	UTC0_ERR	UTC0 error.
1	RESERVED	Reserved.
2	UTC0_PROT_ERR_INTR	UTC0 protocol violation.
3	RESERVED	Reserved.

The CTSET interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_7 through VPAC_INTD_xxx_VPAC_OUT_5_7 registers. Table 7-85 provides more details on the CTSET events. All CTSET error interrupts are single pulse event signals.

Table 7-85. VPAC Subsystem CTSET Interrupt Events

Register Bit	Interrupt Event Name	Description
4	CTM_PULSE_INTR	Counter Timer Module (CTM) pulse interrupt.

7.7.2.5 VPAC Subsystem SL2 Memory Infrastructure

The SL2 memory subsystem implements an interconnect between DMA and HWAs initiators. It contains 512KB Shared L2 memory to acts temporary local memory to transfer data between external memory and HWAs.

The SL2 memory does not implement ECC, as it contains mostly pixel data.

7.7.2.6 VPAC Subsystem DMA Infrastructure

Two UTC instances are used inside the VPAC subsystem. UTC0 deals with real time (RT) transfer , and UTC1 is used for non-realtime (NRT) transfer. Both UTC0 and UTC1 data transfer channels are used for DMA transfers in and out of the VPAC SL2 memory. All 32 channels of the UTC0 are mapped on *channel_number = [95:64]* and are recommended to be used for real time data transfer only. All 64 channels of UTC1 are mapped on *channel_number = [63:0]* and are recommended to be used for all other DMA transfer needs of the VPAC subsystem.

All data movement transactions at VPAC subsystem boundary are multiples of aligned 128-byte transfers.

7.7.2.7 VPAC Subsystem Data Formats Support

Table 7-86 summarizes the data formats supported in VPAC Subsystem.

Table 7-86. VPAC Subsystem Data Formats Support

No	Module	Input			Output

7.7.2.8 VPAC Subsystem Debug Features

The VPAC subsystem is a combination of multiple asynchronous pipelines running concurrently. The Counter, Timer and System Event Trace (CTSET) module within the VPAC susbystem provides the following main features:

- Monitoring up to 255 VPAC events.
- ATB interface compliant trace packets (synchronous to VPAC clock domain).
- Counter (count=8) and Timer (count=4).
- All debug events can be configured to be either selected for trace packet, timer or counter features.
- In one of the combination, debug events can be selected to for timer event out to be used to generate external CTI compliant trigger.

For more information on the CTSET module operation, see Chapter *On-Chip Debug*.

Table 7-87 lists the VPAC subsystem events that are mapped on the CTSET module.

Table 7-87. VPAC Subsystem CTSET Event List

Index	Event Name	HWA	Event Type	Event Description
0	viss_err	VISS0	pulse	VISS Related Error message (config, ovf, sync, blank, access, vp) (1)
1	rawfe_h3a_pulse_intr	VISS0	pulse	H3A interrupt
2	rawfe_dbg_ctl_vs_event	VISS0	pulse	Vertical start in the beginning of the RAWFE pipeline
3	rawfe_dbg_ctl_ve_event	VISS0	pulse	Vertical end in the beginning of the RAWFE pipeline
4	rawfe_dbg_ctl_hs_event	VISS0	pulse	Horizontal start in the beginning of the RAWFE pipeline
5	rawfe_dbg_ctl_he_event	VISS0	pulse	Horizontal end in the beginning of the RAWFE pipeline
6	rawfe_dbg_ctl_lse_slv_stall_event	VISS0	pulse	RAWFE is stalling lse target interface due to FCP or MTC stall
7	rawfe_dbg_ctl_lse_mst_stall_event	VISS0	pulse	H3A controller interface to LSE is stalled
8	rawfe_dbg_ctl_lse_intf_stall_event	VISS0	pulse	Within a frame (VS to VE at RFE i/p) LSE is not sending data to RFE
9	rawfe_dbg_ctl_x_y_match_event	VISS0	pulse	X,Y pixel position has reached the start of RAWFE pipeline
10	rawfe_dbg_ctl_dpc_otf_corr_event	VISS0	pulse	DPC OTF corrected a pixel position
11	rawfe_dbg_ctl_pipe_adv_event	VISS0	pulse	Active pipeline advancement

The VPAC subsystem also supports halting an execution pipeline using external or user halt request. Halting a pipeline is achieved by not granting thread start to HWA. Once halted, VPAC waits for an external sync trigger or config resume to restart execution. VISS, and MSC modules halt at line boundary, and LDC halts at block boundary.

The VPAC subsystem supports generic debug capability/features and ARM cross trigger interface for debug triggers:

- Halting the HWA threads on debug request input at logical trigger boundary.
- Continue/restart VPAC from halted state (step/continue) based on external sync trigger and HTS_DBG_CNTL register.
- Debug compliant dbg_attn output after processing external halt request and when VPAC halts debug enabled pipelines.
- CTI (Cross Trigger Interface) compliant out halted trigger after processing external halt request and reaching halted state of VPAC.
- Stalling all pipelines of VPAC (with configurable option to disable impact of debug features on a pipeline).
- Indicate to Host through readable debug_rdy bit in HTS to indicate readiness of HWA resource in case of halted (dbgattn asserted)

The VPAC subsystem debug capability supported is as captured in the HTS_DBG_CAP register. Ext_halt, ext_sync, hwa_halted are CTI (Cross Trigger Interface) mapped async trigger interface (refer to the async protocol of trigger interface in the ARM® CoreSight™ Architecture Specification).

The VISS module, when used in OTF mode, must not be included as debuggable module within VPAC. VISS must be disabled (HTS: debug pipeline disable) to respond to halt request, otherwise behavior is undefined. The VISS module, when used in memory to memory mode, can be halted. But VISS LUTs must not be read during halted state, as it can corrupt the design pipeline.

7.7.2.9 VPAC Subsystem Security Features

The VPAC subsystem implements region based firewall on target endpoints within config CBASS and SL2 CBASS. Both CBASS is driven by independent DMSC FW interface from SoC level. All internal controllers on SL2 SCR are configured with ISC. Figure 7-23 provides FW/ISC summary.

7.7.3 VPAC Vision Imaging Subsystem (VISS)

This chapter describes the Vision Imaging Subsystem (VISS).

7.7.3.1 VISS Top Level

This section describes the Vision ISS (VISS) top level details.

7.7.3.1.1 VISS Features

The VPAC includes the following processing and infrastructure sub-modules:

Vision Imaging Sub-System (VISS). The vision imaging pipe does image processing on raw data which includes Wide Dynamic Range (WDR) merge, Defect Pixel Correction (DPC), Lens Shading Correction (LSC), Global/ Local Brightness and Contrast Enhancement (GLBCE), demosaicing , color conversion, and Edge Enhancement (EE). It can operate on sensor data either on-the-fly or in memory-to-memory mode. The VISS provides the following main features:

- Performance is 1 pixel per cycle
- Up to 16-bit input RAW formats
- Support for concurrent 12-bit and 8-bit YUV output
- Support for multiple RAW formats (Bayer, RCCB, RCCC, 4x4 RGB-IR, etc.)
- Flexible to handle any 2x2 RAW format
- Support for other color spaces:
  - RGB output
  - Support for color saturation and gray scale for HSV/HSL, etc. (Hue is not supported)
- Support for multiple WDR /HDR Formats and Up-to 3 exposures merge
- Companded format (12 & 14 bit formats)
- Stagger format of WDR
- Split pixel format of WDR
- Rest of WDR format
- Support of statistics for Auto-Exposure / Auto-white-balance or Auto-Focus (configurable option to select either AE/AWB or AF not both concurrently)
- Advanced Spatial Noise filter with 16-bit support
- Dynamic White balance adaptation
- Histogram on Raw Bayer data
- Support for Flexible CFA for generating multi-plane output for any 2x2 RAW Format sensor configuration
  - Supports RCBC, RCCC, Bayer, RGBC as well as other formats
  - Can generate up to 4 independent color planes
  - Support for up two 3 directions per color plane
  - Adaptive Threshold based on intensity measure
- Support for multiple color format output generation
  - Support traditional 12 bit YUV Output
  - Supports RGB output
  - Supports Saturation outputs (8 bits only)
  - Supports Grayscale/Luma/IR/Clear Output
- Support for flexible output format generation including YUV as well as custom
- Support for RGB-IR (4x4) CFA pattern
  - Supports OTF DPC and LSC
  - Supports IR decontamination of the Red, Green Blue channels
  - Supports upto 16-bit IR and YUV outputs
- Edge enhancement Option to bypass visual enhancement functions (NSF4V and GLBCE) for ADAS vision applications
- Concurrent Human Vision (HV) and Mission Vision(MV) outputs
- Chromatic Abaration Correction

Copyright © 2026 Texas Instruments Incorporated

7.7.3.1.2 VISS Block Diagram

The VISS module does on-the-fly processing on raw pixels captured from camera sensor (via CSI RX module). It also does memory to memory processing (via DDR memory) for data captured from other sources at SoC level. Figure 7-24 is simplified block diagram of VISS top level.

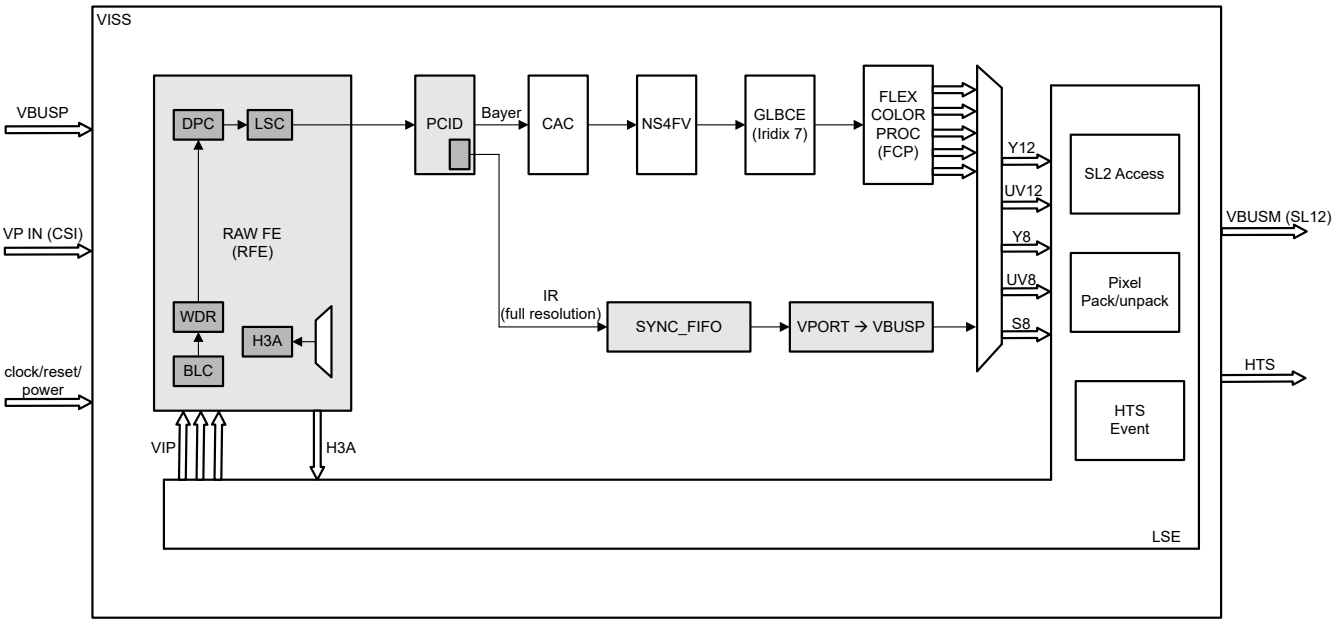

Figure 7-24. VISS Block Diagram

The VISS consists of the following Hardware Accelerators (HWAs):

- RFE (RAW-FE): The RAW Frond End HW block does RAW pixel (that is, Bayer, RCCC, RGBW, etc.) processing on captured image data from sensor and pass-on to NSF4V, GLBCE block, and then to Flexible Color Processing (FCP) HW block for demosaicing and color conversion.
- PCID (Pattern Conversion and IR Demosaicing): Generates full resolution Bayer and IR image from source 4x4 RGB-IR image and performs IR subtraction from the Bayer data. PCID will be enabled in case of when processing 4x4 RGB-IR image.
- CAC: Performs Chromatic aberration correction on Red and Blue pixels. CAC IP can be bypassed in the applications where Chromatic aberration correction is not required.
- NSF4V: Spatial Noise Filter supporting generic 2x2 pixel format with 16-bit pixel size. The NSF4V module can be bypassed in the applications where visual enhancement is not desired.
- GLBCE: The GLBCE module is used for dynamic range control within image for visual quality. If contrast enhancement on input image is required for visual quality, the RFE output is processed by the NSF4v and GLBCE blocks. Otherwise, the RFE output is bypassed to FCP.
- FCP: The Flexible Color Processing HW receives data from the GLBCE and does demosaincing and color conversion. The output of FCP is sent to VPAC shared memory to be written into DDR for the rest of the vision processing by programmable processors (for example, DSP or Arm), or other Vision HW blocks (for example, DMPAC).
- LSE: The Load and Store Engine is and infrastructure block, which performs the following functions:
  - CAL video port: The CSI RX module at SoC level receives CSI-2 sensor data, extracts pixels and drives the result data on its video port interface. The video port is mapped onto one of LSE input interfaces for on-the-fly image processing to reduce DDR bandwidth and latency. The LSE also provides horizontal and vertical blanking cycles to allow core data path to settle at proper boundary of line and frame.
  - SL2 memory access: This module supports load/store data from/to SL2 using VBUSM interface. Loaded data from SL2 are passed on to unpacker function of LSE for RFE. Packed data after FCP/H3A processing is written into SL2.

Copyright © 2026 Texas Instruments Incorporated

- Pixel pack/unpack: Source data (512-bit) for RFE processing is loaded from SL2 and passed onto unpacker function for pixel extraction. Extracted pixels are driven on to the video port of RFE. Similarly, the FCP produced pixels are passed through packer function for eventual write into SL2. The H3A generated data is pseudo mapped as pixels of 32-bit for packing purpose and directly driven by the RFE.
- Event control: The HTS events are generated at line level. These events are routed to LSE to start the processing. For each consumed line, the HTS needs a *task done* indication. For some initial lines of image, there would not be any valid data output. Similarly, the H3A generated data will be at paxel/window height number of lines. For initial lines not producing any valid data, the HTS needs to be indicated with separate mask bits for each output streams. For these initial lines, when there is no valid output due to lines delay inside VISS, the LSE still generates mask output to HTS indicating lack of proper output data.

7.7.3.1.3 VISS Data Flow within VPAC

VISS receives data from sensor through:

- CSI RX video port for OTF processing (Sensor -> CSI RX -> LSE -> RFE -> PCID/CAC/NSF4V/GLBCE -> FCP)
- DMA of VPAC (Sensor -> CAL -> DDR -> VPAC_SL2 -> LSE -> RFE -> PCID/CAC/NSF4V/GLBCE -> FCP)

7.7.3.1.3.1 VISS On-the-fly Processing

The VISS operation is controlled through a single HTS thread. For details of the HTS operation refer to Section *VPAC Hardware Thread Scheduler (HTS)*. The VISS configuration is valid for a single or multiple frame. External-host manages VISS configuration at end of each frame, if required. The HTS controls image processing between lines and handles managing shared memory for VISS inputs/outputs. Sub-frame processing is not natively supported. SW must configure VISS and HTS to start initialization process before enabling sensor capture. After the initialization sequence, the HTS will generate a start trigger to VISS. The generation of the start trigger depends on the availability of H3A data out buffer and FCP data out buffer inside the SL2 memory.

At this stage, the LSE waits for CSI RX video port (VP) to start sending valid pixels. As and when VP data starts streaming in, it is routed to the RFE video port. As RFE, PCID/CAC/NSF4V/GLBCE, and FCP are running in streaming mode, the FCP indicates to LSE about completion of one line of operation . After receiving valid data out, the HTS will trigger UTC for data store into DDR. Each 'thread done' accompanies output mask for all output buffers. Mask bits indicate to HTS about validity of output buffer as for each thread done all output buffers do not need to be produced. The HTS will issue next start after checking all output buffers availability. The streaming data from CSI RX is stallable upto 2KB storage inside VP memory of CSI RX. Any temporary stall can be absorbed, but prolonged stall is buffer overflow inside CSI RX. In VPAC, VISS produced data is transferred using Real Time fabric and low predictable latency needs to be guaranteed.

Copyright © 2026 Texas Instruments Incorporated

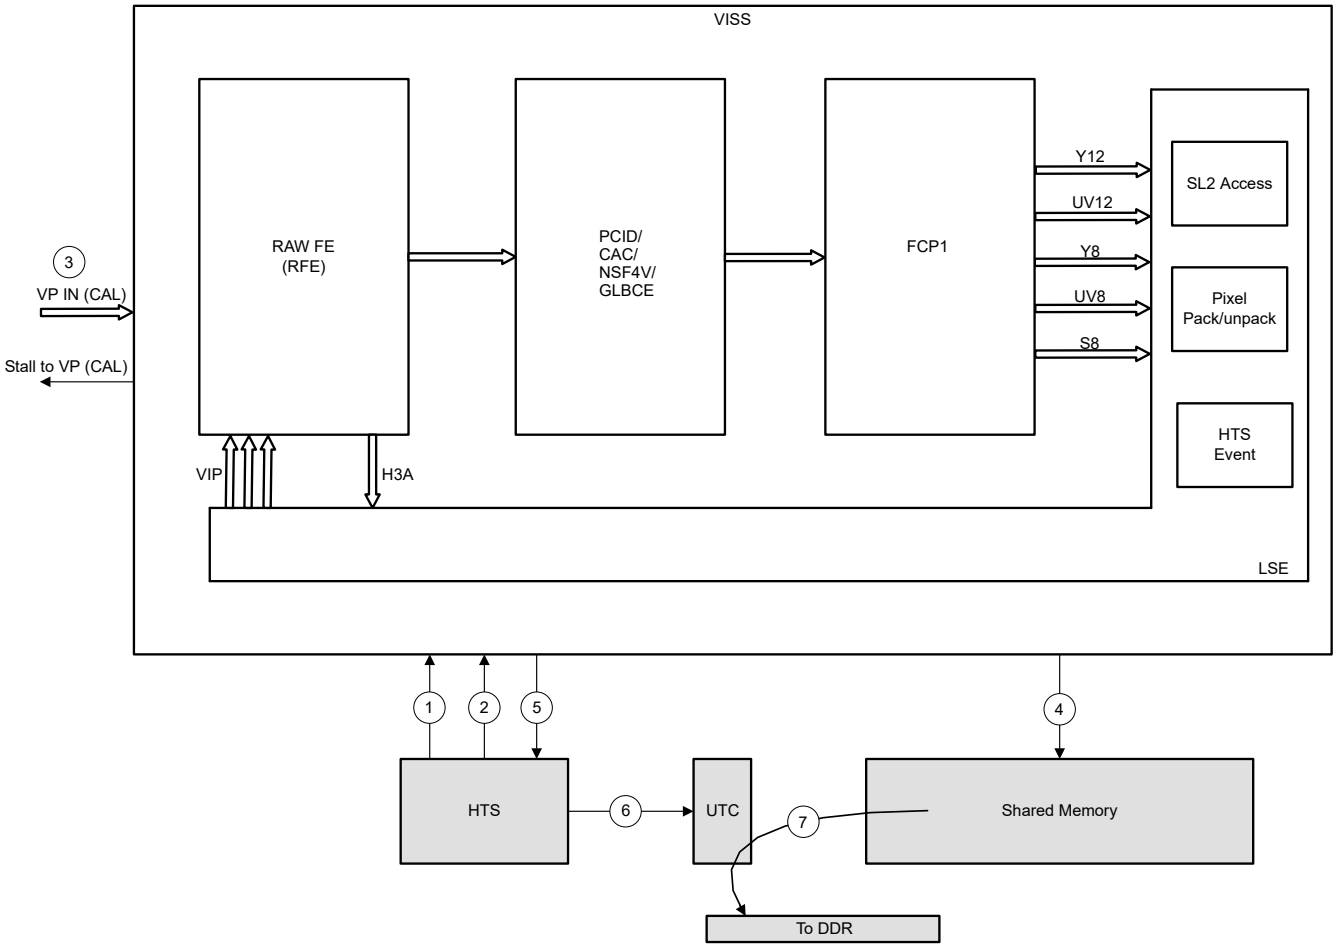

Figure 7-25. VISS On-the-fly Operation

The following OTF operation steps are illustrated in Figure 7-25:

1. *Init* from HTS to initialize VISS.
2. Thread start. Step 1+2 prior to enabling CSI RX + PHY + sensor.
3. Video port data streaming. Unit of operation inside VISS at line level.
4. Output data produced by FCP and H3A at line level. H3A will produce data only at those lines which aligns with paxel_height/window_height.
5. Production of 1 line depends on consumption of 1 line on VP interface. 'Thread done' triggered after completion of 1 processed line write into SL2. In case there is no valid data to be written into SL2, 'thread done' is generated after consumption of 1 line of data from VP. Note: *Horizontal blanking will be configured inside LSE to fecilitate writing complete line out of FCP*.
6. HTS triggers DMA to store output buffer from SL2 to DDR.
7. DMA loads data from SL2 and writes into DDR.

The following assumptions are made for the OTF operation described above:

- UTC write is mapped onto Real Time Thread for guaranteed QoS. Channel done by UTC must be generated after completion of write into DDR. Next thread start depend on availability of minimum one buffer for each output line in SL2. More buffers in SL2 can take care of instantaneous drop in UTC transfer capacity.
- Cycle gap between HTS done and next start must be minimal. CSI RX VP interface will be stalled whenever LSE input buffer on VP interface reaches near full condition.
- Configurable vertical latency times 'Tstart' generated by HTS to let RFE + NSF4V + GLBCE + FCP flush its internal pipe, even though last line of current frame is already fed into RFE.

Copyright © 2026 Texas Instruments Incorporated

- Buffer dependencies:
  - H3A output buffer (AE or AF)
  - FCP output buffer (Y12, YV12, Y8, UV8, S8 or IR)

7.7.3.1.3.1.1 Non-WDR or Companded WDR Sensors

VISS is enabled for single input data when either sensor does not support WDR or sensor does on-chip WDR merge and pass on merged data after companding to 12 bit / 14 bits as shown in Figure 7-26.

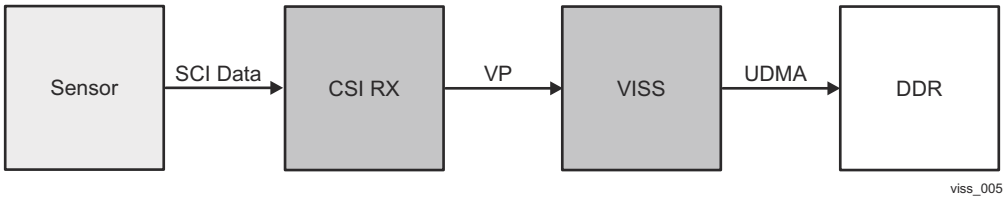

Figure 7-26. VISS Non-WDR/Companded: High Level

7.7.3.1.3.2 VISS Memory to Memory Image Processing

CSI RX writes CSI-2 received pixel data into DDR. Once a frame is written, host is triggered to initiate VISS processing. HTS will go through 'init' sequence to initialize VISS and its SL2 pointers. As UTC is head of pipeline for memory to memory mode of image processing, its scheduler inside HTS needs to be configured for generating "frame height" number of triggers to fetch image lines one by one. This is essential to bring determinism in pipeline as there is no producer for UTC load thread.

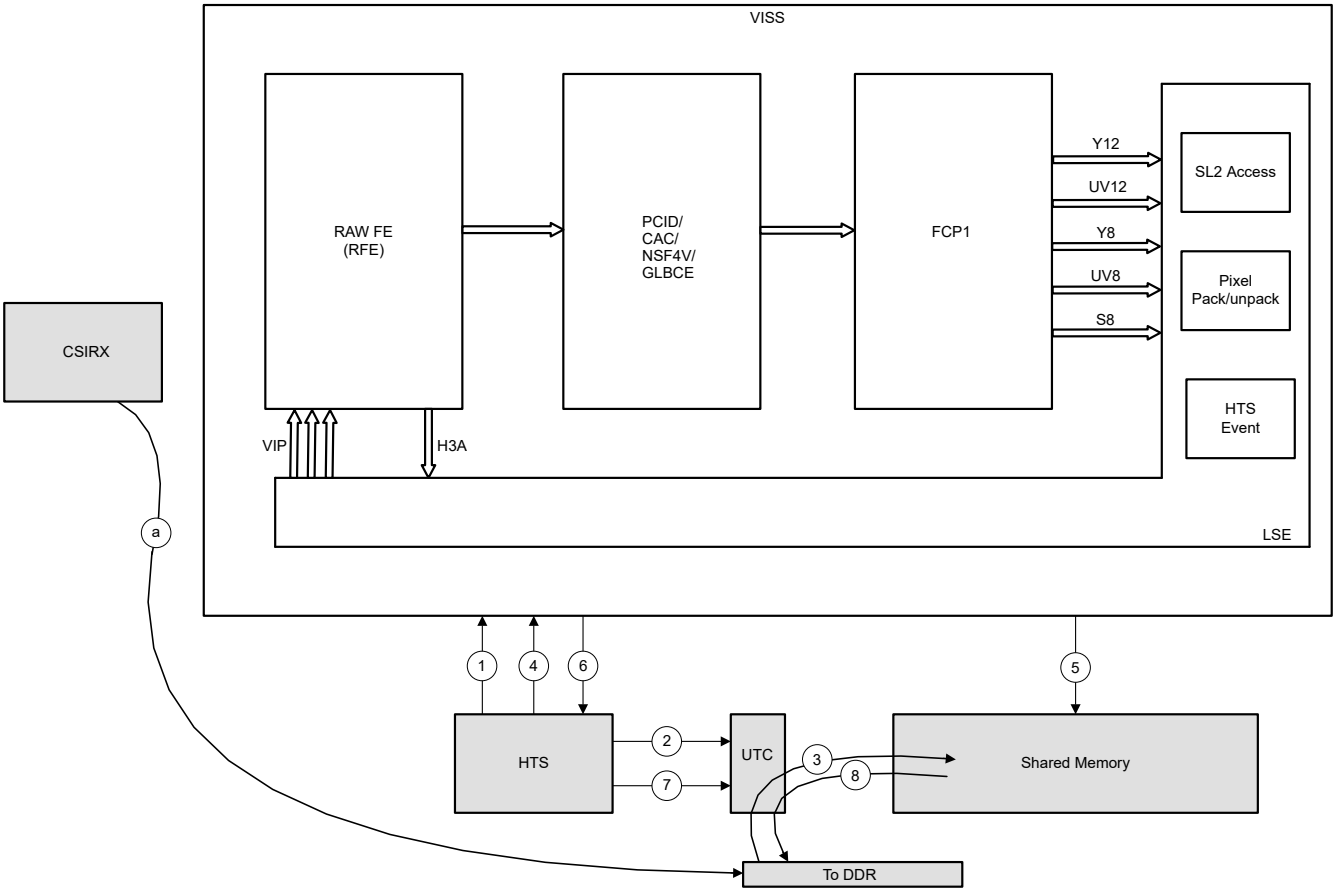

Figure 7-27. VISS Memory to Memory Operation

Copyright © 2026 Texas Instruments Incorporated

The following memory to memory operation steps are illustrated in Figure 7-27:

1. CSI-2 stream captured via CSI RX into DDR. This traffic must be routed through Real Time fabric. CSI RX capture happens independent of VISS processing.

1. *Init* from HTS to initialize VISS.
2. HTS triggers UTC to fetch data for processing. There could be max 3 independent input data.
3. UTC loads the data and stores into SL2.
4. Upon completion of all input buffer loading (at line level) UTC channel 'done' event triggers VISS thread start (still needs to ensure there are buffer available for writing VISS output data).
5. VISS produces line #N corresponding to loading of line #N + vertical_latency.
6. 'Tdone' triggered to HTS.
7. HTS triggers UTC for output buffer transfer into DDR.
8. UTC loads data from SL2 and write into DDR.

The following asumptions are made for the memory to memory operation described above:

- CSI RX write is mapped onto hard real time fabric.
- Configurable vertical blanking times 'Tstart' generated by HTS to let RFE + NSF4V + GLBCE + FCP flush its internal pipe, eventhough last line of current frame is already fed into RFE.
- Buffer dependencies:
  - RFE input buffer (exp0, exp1, exp2)
  - H3A output Buffer (AE or AF)
  - FCP output Buffer (Y12, UV12, Y8, UV8, S8)

7.7.3.1.4 VISS Data Formats Support

Table 7-88 lists the data formats supported by VISS. VISS does not support YUV Input. In case of external YUV Sensor, CSI RX directly writes into DDR and tha data is subsequently processed by the rest of VPAC.

Table 7-88. VISS Data Formats

Direction	Pixel Width	Pixel Container Width (M2M)	Packing	Video port (OTF)	Comments
VISS Input	RAW12/14/16	16b	No	16b / pixel	1. Companded data/External ISP 2. MSB bits are padded with zeros within fixed width pipeline
	RAW8	8b	Yes	16b / pixel	
	RAW12	12b	Yes	16b / pixel	
VISS Output	YUV420 (12b) NV12	12b	Yes	N/A	
	YUV420 (12b) NV12	16b	No	N/A	
	YUV420 (8b) NV12	8b	Yes	N/A	
	YUV422 (8b) UYVY/YUY2/NV16	8b	Yes	N/A	
	RGB (planar)	8b	Yes	N/A	With RGB output, limited YUV data outputs are available (only 12-bit YUV data is available)
	S8	8bit	Yes	N/A	
	IR	8-bit	Yes	N/A	
		10/12-bit	Yes	N/A	

Copyright © 2026 Texas Instruments Incorporated

7.7.3.1.5 VISS VPORT Interface

The video port (VPORT) interface is used to stream the pixel data from up stream to down stream module. In VISS, the VPORT interface is used to receive data from CSI RX (in streaming mode) and in between VISS sub-modules (RFE -> PCID -> CAC -> NSF4V -> GLBCE -> FCP).

The VPORT supports stall signal (VP_STALL) and also either one pixel or 2 pixel data per cycle.

The pixel data (VP_DATA) received on the VPORT is organized in 32 bits as follows:

- VP_DATA[15:0] = pixel (n)
- VP_DATA[31:16] = pixel (n+1). This is ignored, when VPORT_TWO_PIXEL = 0
- MSBs are padded with 0's when less than 16 bits are used.

7.7.3.1.6 VISS Submodule Integration Specifics

7.7.3.1.6.1 LSE Integration

Figure 7-28 captures the channel integration between LSE and rest of VISS submodules. Though digram shows three input channels between LSE to RFE, 3 channels data is transferred using single VBUSP interface.

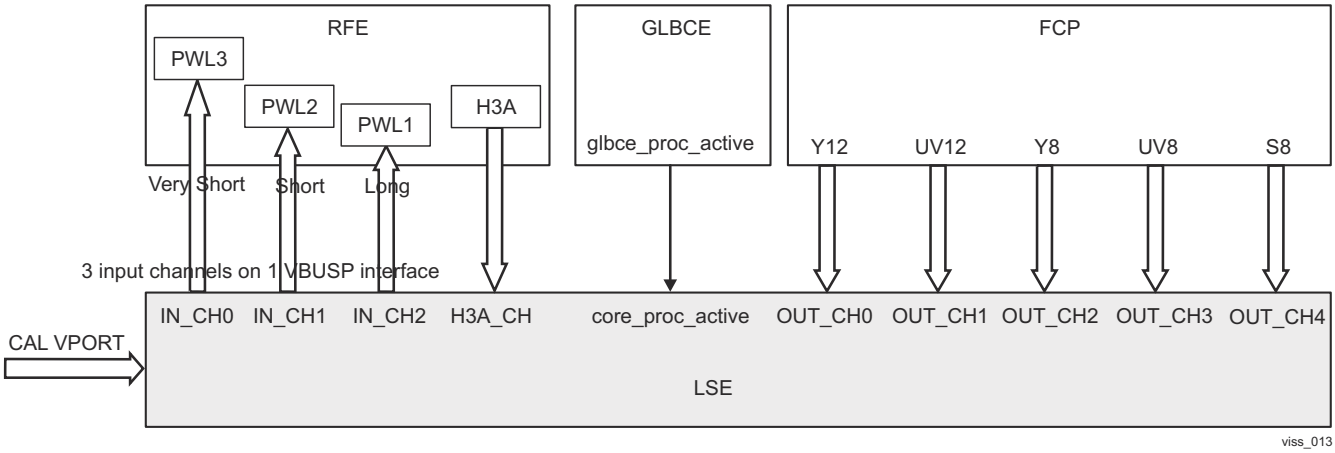

Figure 7-28. VISS LSE Channel Integration

LSE supports YUV422 interleaving only on 8-bit data.

The LSE configuration for VISS can be read in VISS_LSE_STATUS_PARAM register fields.

For more information on LSE module operation, see Chapter *Load and Store Engine (LSE)*.

7.7.3.1.6.2 PCID

Figure 7-24 captures intergration of PCID into VISS. PCID produces both Bayer and IR data concurrently from input RGBIR image. Bayer channel data is fed to rest of the VISS pipe line and IR channel output is directly written to memory using one of LSE channels. VPORT Delay SYNC_FIFO supports programbale horizontal delay to match the delay with FCP output.

7.7.3.1.6.3 Chromatic Aberration Correction

Figure *CAC, NSF4V, and GLBCE Integration* captures the CAC, NSF4V, and GLBCE integration in the VISS pipeline. All CAC, NSF4V, and GLBCE can be enabled or disabled based on use case. By default, all are disabled. General visual use cases require NSF4V and GLBCE (along with FCP.EE) to be enabled. Lenses with purple fringe artifact require CAC to be enabled.

Copyright © 2026 Texas Instruments Incorporated

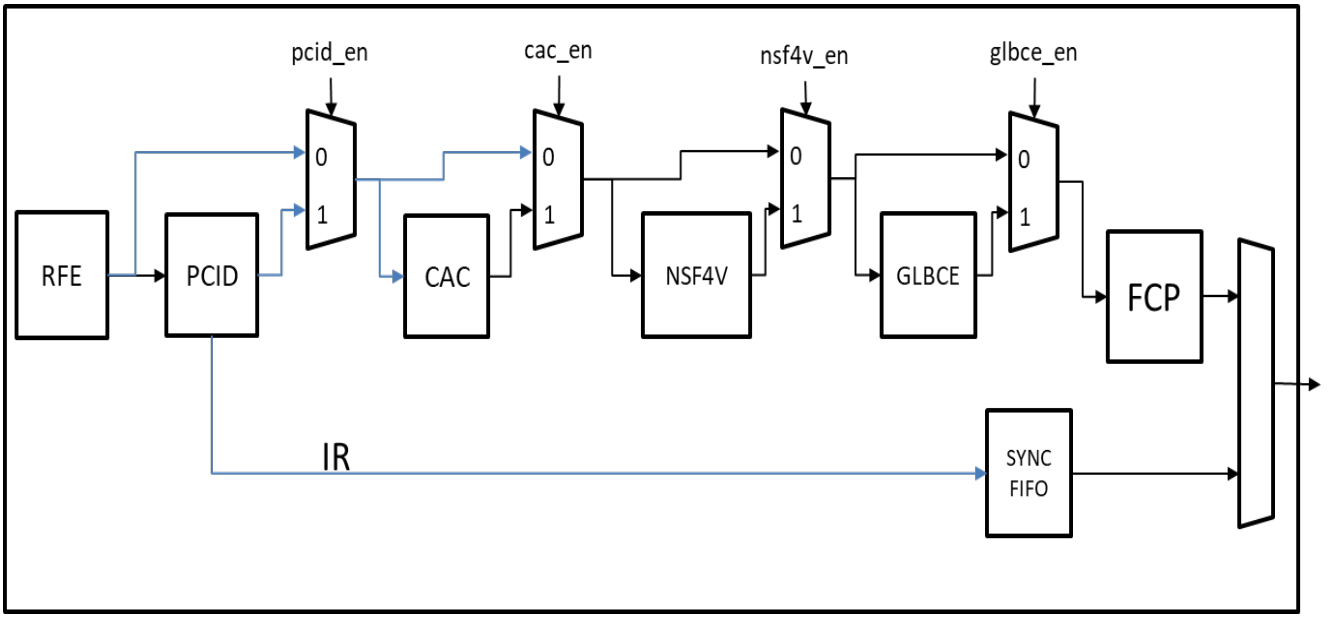

Figure 7-29. CAC, NSF4V, and GLBCE Integration

7.7.3.1.6.4 GLBCE Integration

GLBCE is Global/Local Brightness and Contrast Enhancement module.

The GLBCE module supports the following main features:

- One pixel/cycle operation
- Up to 4096 pixels/line (line size)
- Bayer image
- When GLBCE is off, the RFE/NSF4V output is bypassed to FCP

For more information on GLBCE operation, see Section 7.7.3.7, *VISS Global/Local Brightness and Contrast Enhancement (GLBCE) Module*.

7.7.3.1.6.4.1 GLBCE Startup

GLBCE requires approximately 5400 clock pulses after startup before it could receive data on its video port. Therefore, before RFE -> GLBCE -> FCP path could be used after a GLBCE reset, the SW shall use the following sequence to provide those required clock pulses:

- Prior to enabling rest of VISS pipe, configure VISS clock control to allow free running clock to GLBCE.
- Wait for the 'glbce_filtering_done' event. It indicates that GLBCE has received enough PCLK pulses for internal initialization and that it is now ready to receive pixels.
- Configure GLBCE clock to normal mode. Enable the rest of VISS pipeline.

GLBCE has a minimum input restriction of 480x240 pixels. The input frame must be at least this size.

GLBCE LUTs must not be changed during the active frames. They can only be updated in vertical blanking. GLBCE_LUT_FI may be changed frame by frame depending on the GLBCE tuning method. Other LUTs (GLBCE_REV_PERCEPT_LUT_xx, GLBCE_FWD_PERCEPT_LUT_xx, and GLBCE_WDR_GAMMA_LUT_xx) are not expected to be updated dynamically except in very limited case.

7.7.3.1.6.4.2 GLBCE Bypass

When the GLBCE is disabled (by VISS_CNTL[0] GLBCE_EN = 0), any access targeted to GLBCE registers or GLBCE statistics memory will respond with error status, and 'glbce_cfg_err' interrupt will be generated.

Copyright © 2026 Texas Instruments Incorporated

7.7.3.1.7 VISS Stall Handling

VISS can handle momentarily stall condition created due to lack of enough band width. Streaming mode is described in the following sections.

7.7.3.1.7.1 Stall Handling for Streaming Mode

Streaming stall handling is similar to memory to memory mode, except that final effect will be reflected in generating stall to the VPORT interface. Upon stall assertion, VISS expects no more than 2 VPORT pixel clock cycles.

7.7.3.1.8 VISS Blanking Requirements

Table 7-89 lists some blanking and latency details for VIS submodules.

Table 7-89. VISS Blanking Requirements

IP	Blanking		Latency	
	Vertical (in number of lines)	Horizontal (in pixel clock cycles)	Vertical (in number of lines)	Horizontal (in pixel clock cycles)
RawFE (2x2)	2 - DPC Enable 0 - DPC Disable	8	2 - DPC Enable 0 - DPC Disable	50
RawFE (4x4 RGBIR)	4 - DPC Enable 0 - DPC Disable	10	4 - DPC Enable 0 - DPC Disable	53
PCID	4	27	4	27 (Bayer Out)(3) 30 (IR Out)
CAC	6	20	6	24
NSF4V	15	28	15	44
NSF4V.DWB	0	7	0	7
GLBCE	- (1)	5	1	62
CFA	1	5	3	25
FCC	0	20	1 (2)	25
EE	2	2	2	29

(1) GLBCE requires (1033*7 + 2066*FLOOR(VARIANCEINTENSITY/2,1) + VARIANCESPACE*2066+30) cycles for vertical blanking.
(2) In 420 mode, Chroma is vertically downsampled. For the first line, Chroma channel does not generate any dummy VBUSP requests. Hence, 1 line vertical delay is required.
(3) It is latency of the physical channel not the data type. If IR data is selected to Bayer channel, Bayer channel output latency remain the same (i.e. 27)

The VARIANCEINTENSITY and VARIANCESPACE parameters (in Table 7-89 notes) affect the sensitivity of the transforms across different parts of the frame. Both parameters can be configured through the GLBCE_VARIANCE register.

In Table 7-89, the vertical blanking/latencies are expressed in number of lines (except for GLBCE), and horizontal blanking/latency is expressed in number of pixel clock cycles.

Horizontal blanking, buffer depth and HTS programming parameters (Threshold and PostLoad) depend on VISS frame mode or line mode of operation (selected via LSE_CFG_LSE[5] IN_CH_SYNC_MODE register field). Frame mode is the recommended mode of operation, and line mode is primarly used for debug purposes.

- Frame mode:
  - LSE input line fetch starts once the previous input line plus horizontal blanking cycle are provided to RFE. Horizontal blanking should meet two requirements:
    - Greater than minimum horizontal blanking of each enabled modules
    - Greater than maximum cycle gap between the last line pixel write on all LSE enabled output channel line ends
  - Horizontal Blanking of 35 is expected to be sufficient for most use cases. Horizontal blanking of 55 should be used, if EE is enabled and any of the CFA outputs is directly written out.
- Line mode:

Copyright © 2026 Texas Instruments Incorporated

  - LSE input line fetch start on HTS Tstart
  - Horizontal blanking is addition of all enabled modules horizontal delay (that is, latency)

LSE will automatically generate required vertical blanking until all output channels produce HTS_EOP, and GLBCE processing is complete (when GLBCE is enabled). In the vertical blanking window, LSE generates dummy lines (data = 0x0) following frame width paramter. LSE prematurely ends line w/o HE marker once vertical blanking requirement is met (that is, processing is done and HTS_EOP is generated).

7.7.3.1.9 VISS Interrupts

The VISS submodules generate the interrupt events described in Section *VPAC Subsystem Interrupts*.

7.7.3.1.9.1 Interrupts Merging

The configuration error interrupts are merged at VISS level. The following list describe the configuration error eventss and the corresponding merged interrupts.

- RAWFE_CFG_ERR_INTR: Generated when configuration interface access the RFE end points, while frame processing is active. Merged interrupts from RFE:
  - lut1_cfg_err_intr
  - lut2_cfg_err_intr
  - lut3_cfg_err_intr
  - wdr_lut_cfg_err_intr
  - dpc_line_cfg_err_intr
  - dpc_lut_cfg_err_intr
  - h3a_lut_cfg_err_intr
  - h3a_line_cfg_err_intr
  - h3a_accm_cfg_err_intr
  - lsc_cfg_err_intr
- GLBCE_CFG_ERR_INTR: Generated when the configuration interface access the GLBCE register region or statastics memory, while frame processing is active. Merged interrupts from GLBCE:
  - glbce_statmem_cfg_err_intr
  - glbce_mmr_cfg_err_intr
- FCFA_CFG_ERR_INTR: Generated when the configuration interface access the CFA register region, or LUT or line memory, while frame processing is active. Merged interrupts from CFA:
  - clut_cfg_err_intr
  - dlut_cfg_err_intr
  - lut_cfg_err_intr
  - cfa_mmr_err_intr
  - cfa_pix_err_intr
- FCC_OUTIF_OVF_INTR: FIFO Overflow happened at output interface between FCC and LSE. Merged all FCC output overflow error sources at VISS. Refer to Section VISS Flexible Color Processing (FCP) for all sources.
  - overflow_if_y12_intr
  - dlut_cfg_err_intr
  - lut_cfg_err_intr
  - cfa_mmr_err_intr
  - cfa_pix_err_intr
- FCC_OUTIF_OVF_ERR_INTR: Generated when any of the FCC output interfaces overflows. Merged interrupts from CC:
  - overflow_if_y12_intr
  - overflow_if_uv12_intr
  - overflow_if_y8r8_intr
  - overflow_if_c8g8_intr
  - overflow_if_s8b8_intr
  - overflow_if_irout_intr

Copyright © 2026 Texas Instruments Incorporated

- FCC_CFG_ERR_INTR: Generated when the configuration interface access FCC register region or its LUTs, while frame processing is active. Merged interrupts from FCC:
  - contrast0_cfg_err_intr
  - contrast1_cfg_err_intr
  - contrast2_cfg_err_intr
  - lut_12to80_cfg_err_intr
  - lut_12to81_cfg_err_intr
  - lut_12to82_cfg_err_intr
- EE_CFG_ERR_INTR: Configuration happened to EE regions causing corruption during frame processing. Merged EE sources are:
  - eelut_cfg_err_intr
  - ee_pix_err_intr
- EE_SYNCOVF_ERR_INTR: EE horizontal synchronization FIFO overflow interrupt:
  - ee_hz_align12_intr
  - ee_hz_align8_intr

7.7.3.1.9.2 Handling of Configuration Error Interrupts

Table 7-90 give hints on handling configuration error interrupts.

Table 7-90. VISS Configuration Error Interrupts Handling

Memory	Error Generation Window	HWA-level Register Status Clearing Mechanism
RAWFE		
PWL1_LUT, PWL2_LUT, PWL3_LUT	Config read access during active line OR write access during active frame.	Write ‘1’ to corresponding bit in RAWFE_INT_STAT register.
WDR_LUT		
H3A_LUT		
H3A_ACCM	Config read/write access during active frame at H3A boundary.	
H3A_LINE		
DPC_LUT	Config read/write access during active frame.	
DPC_LINE	Config read access during active line OR write access during active frame.	
LSC Table	Config read/write access during active frame. Active frame in lsc case is VS at pwl to VE at lsc input delayed by 1 cycle.	
NSF4V		
NSF4V_LINE	Config read/write access when datapath is accessing the corresponding memory on the same cycle.	No register status in NSF4V.
GLBCE		
GLBCE non-shadowed registers	Config write access during active frame. Active frame window is from VS_IN to Filter done.	Write ‘1’ to GLBCE_INT_STAT[0] MMR_CFG_ERR register bit.
GLBCE_STAT	Config read/write access during active frame. Active frame window is from VS_IN to Filter done.	Write ‘1’ into GLBCE_INT_STAT[1] STATMEM_CFG_ERR register bit.
GLBCE_LINE	Not mapped to config.	N/A
CFA		
CFA FIR Filter registers	Config write access during active frame.	Write ‘1’ to CFA_INT_STATUS[2] CFA_MMR_ERR register bit.
CFA_LUT	Config read/write access during active frame.	Write ‘1’ into CFA_INT_STATUS[0] LUT_CFG_ERR register bit.
CFA_LINE	Config read/write access during active frame.	Write ‘1’ to CFA_INT_STATUS[1] CFA_PIX_ERR register bit.
FCC		

Copyright © 2026 Texas Instruments Incorporated

Table 7-90. VISS Configuration Error Interrupts Handling (continued)

Memory	Error Generation Window	HWA-level Register Status Clearing Mechanism
LUT_CONTRAST	Config access (read/write) occurs during active line when the LUT is enabled.	Write '1' to corresponding bit in FCC_FLEXCC_INT_STATUS register.
HISTOGRAM	Config access has occurred to the first location but not to the last location till the start of next frame implying that full histogram was not read.	
LUT_COLOR	Config access (read/write) occurs during active line when the LUT is enabled.	
CC_LINE	No error generation logic.	N/A
EE		
EE_LINE	Config accesses during active frame.	Write '1' to EE_INT_STATUS[1] EE_PIX_ERR register bit.
LUT	Config accesses during active frame.	Write '1' to EE_INT_STATUS[0] EELUT_CFG_ERR register bit.

7.7.3.1.10 VISS Error Correcting Code (ECC) Support

ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

One or more memories within VISS are ECC protected using an ECC Memory Wrapper which implements Single Error Correction and Double Error Detection (SECDED).

The ECC wrapper provides Single Error Detection and Correction (SED/SEC). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC wrapper also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC wrapper also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

An ECC Aggregator at the VISS level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. It provides a single EOI-handshake based interrupt to the host (for both single and double error detections) and a standard 32-bit VBUSP interface for configuring and querying the various ECC wrappers via their ECC register set.

The following VISS memories are ECC protected:

- GLBCE statastics memory.
- RAWFE non pixel line buffer memories. See Section *VISS RAW Frond-End (RAWFE)*, for more information.
- FCP non pixel line buffer memories

For more information on the ECC Aggregator operation, see Section *ECC Aggregator* in Chapter *Safety Modules*.

7.7.3.1.11 VISS Programmer's Guide

7.7.3.1.11.1 VISS Initialization Sequence

VISS initialization is part of any other HWA initialization on VPAC. Prior to starting HWA initialization through HTS, VISS must be configured in below order.

1. Configure RFE registers, GLBCE registers, NSF4V registers and FCP registers:
   - The VISS_CNTL[0] GLBCE_EN register bit needs to be set, in order to configure the GLBCE registers.
2. Select input / output stream properties inside LSE.
3. After reset and prior to enabling LSE, apply the following configuration:
   a. Make sure VISS_CNTL[0] GLBCE_EN bit is '1'.
   b. Enable IRQ for interrupt event 'glbce_filtering_done'.
   c. Set VISS_GLBCECONFIG[0] GLBCE_PCLKFREE register bit to '1'.

Copyright © 2026 Texas Instruments Incorporated

d. Wait for interrupt 'glbce_filtering_done'.
e. Clear VISS_GLBCECONFIG[0] GLBCE_PCLKFREE register bit.

4. Enable LSE input and output buffer lines.
5. Enable pipeline and schedulers associated with VISS HTS configuration (pipeline enable must happen after enabling all attached schedulers).
6. Enabling HTS will trigger init sequence which will initialize LSE, RFE and FCP. This will also trigger head of pipe for NAVSS UDMA fetch (in case of memory to memory operation). Otherwise,VISS waits for streaming data from CSI RX.
7. After initializing VISS/VPAC, configure and enable CSI RX, CSI RX PHY and camera sensor in order.
8. Once streaming data starts, it will continue till the end of frame. Blanking (set in VISS_LSE_CFG[31-22] VP_HBLNK_CNT register field) must be configured more than VISS blanking needs (see *VISS Blanking Requirements*).
9. Once a complete frame is fully written into DDR, the HTS module comes back to init state and restart from step #6. For some usesecase, LSE input/out enables after each frame might be considered as well (step #5).
10. After each 'frame_done', if the configuration needs to be changed, it must be done within vertical blanking period for not shadowed registers (refer to Sections *VISS RAW Frond-End (RAWFE)* and *VISS Flexible Color Processing (FCP) Module*, for more details).
11. At any stage, if there is a need to stop the streaming interface, the HTS must first be paused and then aborted, and then reset and re-configure the entire VISS as part or recovery from abort.

7.7.3.1.11.2 VISS Configuration Restrictions

Frame size restriction:

- If GLBCE is enabled in the VISS pipeline, the minimum frame required is 480x240 pixels.
- If GLBCE is disabled in the VISS pipeline, the minimum frame required is 64x16 pixels.
- Frame width and height has to be even.
- Histogram can only be enabled when the frame width is 256 pixels minimum.

LSE H3A channel enabling restriction:

- When the H3A output channel is enabled in LSE, at least one other output channel needs to be enabled.

7.7.3.1.11.3 VISS Real-time Operating Requirements

SW needs to configure UTC/UDMA channel registers for write out buffers.

SW needs to reconfigure RAWFE LSE LUT, if needed, and any other non-shadowed registers during vertical blanking period only. Some control bits would be shadowed, which can be configured during a complete frame.

Copyright © 2026 Texas Instruments Incorporated

7.7.3.2 VISS Load Store Engine (LSE)

For more information on the VISS LSE module operation, see *LSE Integration* and *Load Store Engine (LSE)*.

Copyright © 2026 Texas Instruments Incorporated

7.7.3.3 VISS RAW Frond-End (RAWFE)

This section describes the Vision Imaging Sub-system (VISS) RAW Frond-End (RAWFE) module in the device.

7.7.3.3.1 RAWFE Overview

The RAWFE is a set of raw pixel processing functions to enhance the RAW image signal received from the sensor. The key application of the RAWFE is in the ADAS space where in it is used for both analytics as well as visual use cases.

7.7.3.3.1.1 RAWFE Supported Features

Each RAWFE module implements the following features:

- Support for any 2x2 RAW data pattern.
- Support for 4x4 RGBIR CFA pattern (50% green, 25% IR, 12.5% red and 12.5% blue).
- Support for merge up to 3 separate exposures (non 4x4 RGBIR CFA pattern).
- PWL (piecewise linear) and LUT based de-companding at the front end of each exposure channel.
- Support for WDR merge, including 2 exposure merge, 3 exposure merge and 2 exposure hybrid (12 bit and 16 bit) merge.
- Support for companding LUT from 24 bits down to 12 bits.
  - LUTs support higher precision in lower end.
- Support for LUT as well as adaptive Defective Pixel Correction.
- Support for export of defective pixel coordination in adaptive defect pixel correction mode.
- Support for table based lens shading correction.
- Support for 3A statistics.
  - Statistics can be generated on independent exposures or merged data after tone map.

7.7.3.3.1.2 RAWFE Not Supported Features

The RAWFE does not support the following features:

- Motion compensated WDR Merge
- Simultaneous statistics using H3A on all 3 exposures
- More than 3 exposures for WDR
- Frame size that is not in the 4x4 CFA pattern for RGBIR sensors, or frame height or width which is not integer multiple of 4

7.7.3.3.2 RAWFE Functional Description

7.7.3.3.2.1 RAWFE Functional Operation

The RAWFE processes captured image data from sensor and passes the data to the Flexible Color processing module (FCP) for demosaicing and color conversion.

Figure 7-30 shows a high level conceptual block diagram of the RAWFE module.

The RAWFE consists of the following main components

- Decompanding block: This is used to decompand the sensor compressed raw to native bit depth. The same block can be used for tone mapping as well. The decompanding block can take sensor compressed RAW data and can decompand to up to 24 bits.
- WDR Merge: Each instance of the WDR merge block can take in 2 independent exposures (up to 16 bits) and generate up to 20 bit data.
- LSC Block: The block performs lens shading correction by applying gains stored in a look up memory.
- DPC: The block performs defect pixel correction using either LUT based memory or adaptive defect correction.
- H3A: The H3A block generates 2 different set of statistics, one for AWB and AE and the other for auto focus.
- In addition, when RGBIR sensor is used, H3A can be configured to select PCID output and generate statistics.

Copyright © 2026 Texas Instruments Incorporated

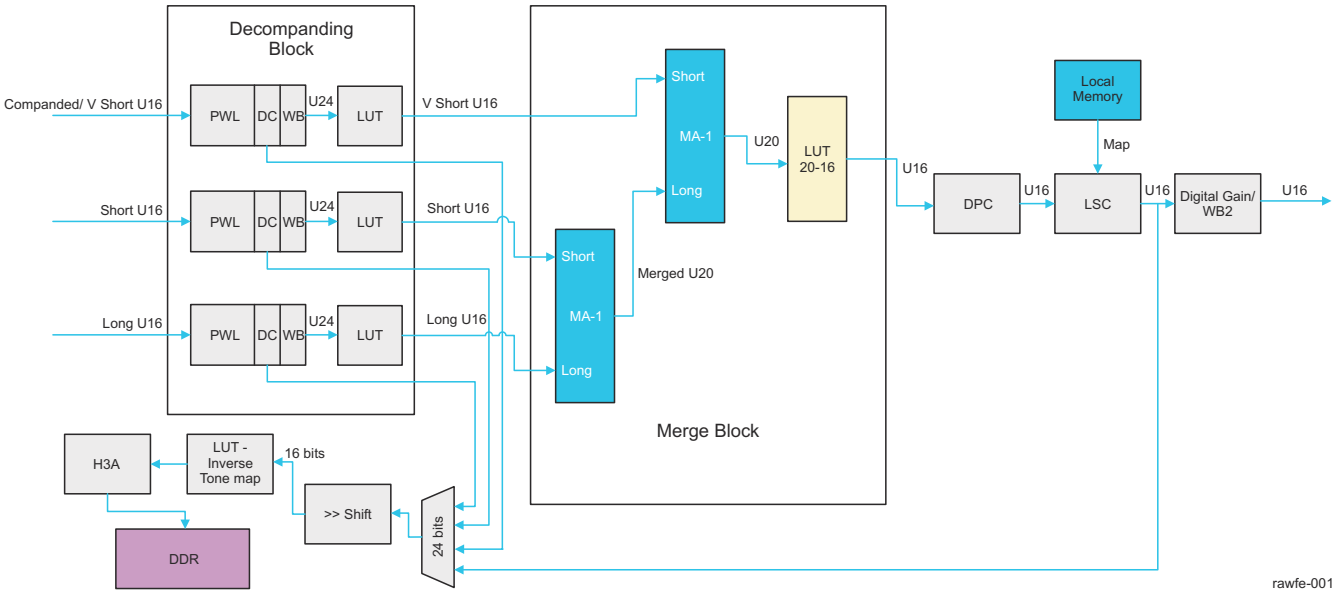

Figure 7-30. RAWFE Block Diagram

7.7.3.3.2.2 RAWFE Integration in VISS

Figure 7-31 show the VISS Block Diagram integrating the RAWFE module.

The VISS Consist of following hardware accelerators

1. RAWFE: The RAWFE block does RAW pixel (e.g. Bayer, Clear Channel, 4x4 RGB-IR) processing on captured image data from sensor and later passes to FCP block for demosaicing and color conversion.
2. FCP (Flexible Color Processing): The FCP receives data from RAWFE and does demosaicing and color conversion. The output of FCP is sent to external memory for vision processing by programmable processors (e.g. DSP or ARM) as well as Vision HW Blocks (e.g. VPAC and DMPAC). If the sensor data is 4x4 RGBIR, output of RAW-FE is first sent to PCID to convert RGB into 2x2 Bayer which is then sent to Flexible Color Processing. Meanwhile, the full resolution IR produced by PCID is sent to external memory.
3. GLBCE (Global Local Brightness and Contrast Enhancement): This is local adaptive tone mapping block for 2x2 RGB either from directly from RAE-FE or converted to 2x2 RGB from 4x4 RGBIR by PCID.

Copyright © 2026 Texas Instruments Incorporated

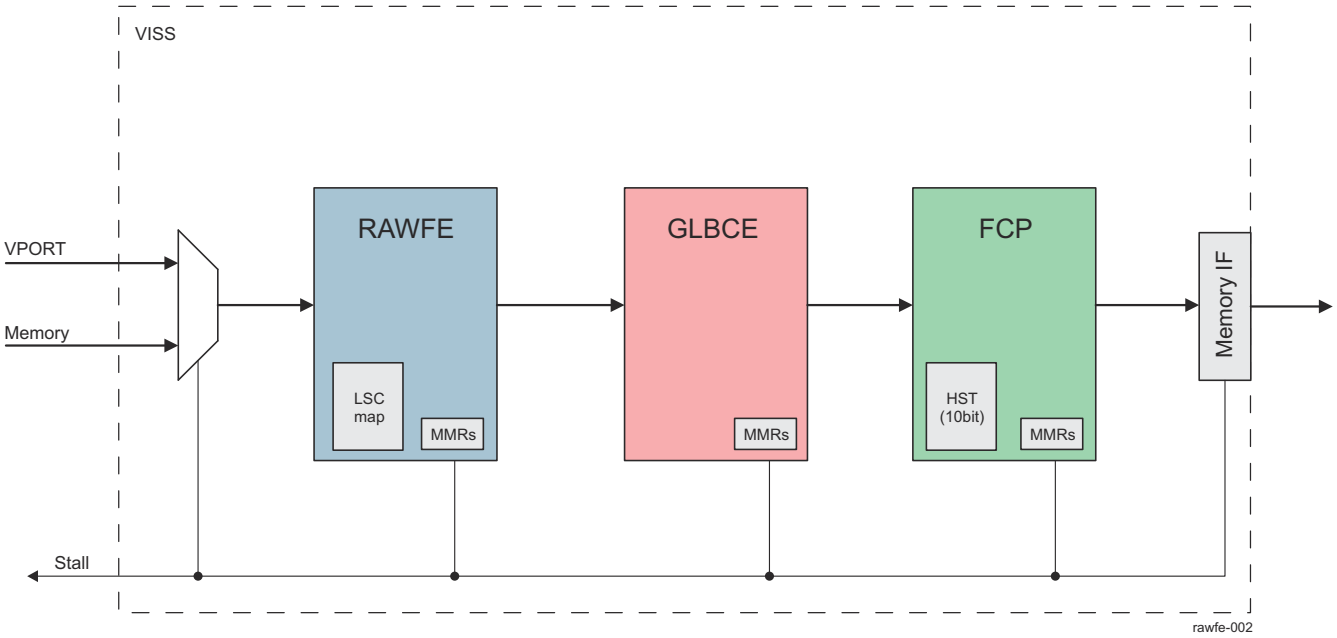

Figure 7-31. RAWFE Integration in the VISS

7.7.3.3.2.3 RAWFE Memory Map

Table 7-91 lists the RAWFE memory mapped RAMs.

Table 7-91. RAWFE Memory Map

Address Offset	Register Space	Size
0x00000	RAWFE registers	
0x00400	H3A registers	
0x00800	V-Short LUT (LUT3-RAM)(1)	639 x 16 bits
0x01000	Short LUT (LUT2-RAM)(1)	639 x 16 bits
0x01800	Long LUT (LUT1-RAM)(1)	639 x 16 bits
0x02000	Merge LUT (WDR_LUT-RAM)(1)	639 x 16 bits
0x02800	H3A LUT (H3a_LUT-RAM)(1)	639 x 10 bits
0x03000	DPC LUT (DPC-RAM)(1)	256 x 29 bits
0x08000	LSC LUT (RAM)(1)	5248 x 39 bits
0x16000	DPC_STAT (DPC_STAT-RAM)	2048 x 26 bits

(1) Partial writes to RAMs are not supported. Software must write the full word. This restriction is an artifact of simplifying ECC support.

Most registers in RAWFE MMR space are shadowed. On frame start, the non shadowed registers will update the shadowed registers and used for the remainder of the frame for data processing. The following registers are not shadowed:

- VISS_RAWFE_INT_STAT
- VISS_RAWFE_DBG_STAT1
- VISS_RAWFE_DBG_STAT2
- VISS_RAWFE_DBG_STAT3
- VISS_RAWFE_DBG_STAT4
- VISS_RAWFE_DBG_CTL

H3A has partial shadowing, refer to Section 7.7.3.3.4.7 for details.

Copyright © 2026 Texas Instruments Incorporated

LUT3 RAM is shadowed. LUT3 and LUT2 will be multiplexed for shadowing capabilities. Software must use a control register to select which LUT is to be used during frame. Software must fully configure LUT2 in this case as well.

Note

Accesses to non shadowed registers or RAMs during active window can cause corruption. During an active phase, non blanking region, any accesses to a RAM, read or write, will corrupt the output data. H3A RAMs, LSC LUT, DPC LUT RAMs are exceptions. These RAMs must be outside the full frame, including horizontal blanking regions, otherwise they will cause corruption. Any write to MMRs that are not shadowed will result in data corruption in non blanking area, the interrupt status and debug registers are exception. MMR reads to any type of register are ok and will not result in frame output corruption. Interrupt events will be asserted if configuration accesses corrupt frame data.

7.7.3.3.2.4 RAWFE ECC for RAMs

Table 7-92 lists the RAWFE ECC RAMs

Table 7-92. RAM ECC Capabilities

Module	# Rams	ECC
PWL LUT1	2	ECC, with single bit correction, including writeback.
PWL LUT2	2	ECC, with single bit correction, including writeback.
PWL LUT3	2	ECC, with single bit correction, including writeback.

H3A line	1	No ECC

7.7.3.3.3 RAWFE Interrupts

The following section lists the RAWFE interrupts

7.7.3.3.3.1 RAWFE CPU Interrupts

Table 7-93 lists the interrupts generated by the RAWFE sub-modules.

Table 7-93. RAWFE Interrupts

Interrupt	Description
LUT1_CFG_ERR	Config access to LUT1 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
LUT2_CFG_ERR	Config access to LUT2 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
LUT3_CFG_ERR	Config access to LUT3 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if cfg access occurs during active line. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.

Copyright © 2026 Texas Instruments Incorporated

Table 7-93. RAWFE Interrupts (continued)

Interrupt	Description
WDR_LUT_CFG_ERR	Config access to WDR LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
H3A_LUT_CFG_ERR	Config access to H3A LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
H3A_ACCM_CFG_ERR	Config access to H3A accum ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
H3A_LINE_CFG_ERR	Config access to H3A line ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
DPC_LUT_CFG_ERR	Config access to DPC LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
DPC_LINE_CFG_ERR	Config access to DPC line ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
LSC_CFG_ERR	Config access to LSC ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame. Active frame in lsc case is VS at pwl to ve at lsc input delayed by 1 cycle. LSC_CFG_ERR interrupt may be disabled by setting DISABLE_LUT_CFG_ERR register bit to '1'.
AEW_PULSE	H3A aew pulse interrupt.
AF_PULSE	H3A af pulse interrupt
H3A_PULSE	H3A pulse interrupt
H3A_BUF_OVERFLOW_PULSE	H3A interrupt generated when an overflow occurs in the H3A output buffer.
DPC_STATS_READ_ERR	This interrupt is set when reading by SW to DPC stats is started after frame n is completed but the last valid stats entry is not read by the end of frame n+1. write 1 to clear event status, write 0 has no affect. To avoid dpc_stats of frame n to be overwritten by frame n+1 processing, DPC_STATS_UPDATE_CFG should be programmed to be 2'b01 and 2'b10 alternately for successive frames.

7.7.3.3.3.2 RAWFE Debug Events

Table 7-94 lists the RAWFE debug events. Debug events are used for hardware debug as well as performance measurement. They are not intended to be used as interrupts where the cpu needs to process them.

Table 7-94. RAWFE Debug events

Event	Description
VS_EVENT	ventricle start in the beginning of the rawfe pipeline
VE_EVENT	ventricle end at the end of the rawfe pipeline
HS_EVENT	horizontal start in the beginning of the rawfe pipeline
HE_EVENT	horizontal end at the end of the rawfe pipeline
LSE_SLAVE_STALL	rawfe is stalling lse target interface due to ext or mtc stall
LSE_MASTER_STALL	lse controller interface is stalled
LSE_INTERFACE_IDLE	within a frame lse is not sending data
X_Y_EVENT_MATCH	x-y pixel position has reached the start of rawfe pipeline
DPC_OTF_CORR_EVENT	dpc otf corrected a pixel position

Table 7-94. RAWFE Debug events (continued)

Event	Description
PIPE_ADV_EVENT	active pipeline advancement

7.7.3.3.4 RAWFE Sub-Modules Details

The following sections describe in detail the sub-modules present within the RAWFE module.

7.7.3.3.4.1 RAWFE Decompanding Block

The decompanding block is responsible for decompanding pwl (or LUT) compressed data back to its linear bit width. The decompanding block can generate up to 24 bits of data, however the data needs to be tone mapped down to 16 bits before additional processing can take place. There are 3 instances of the Decompanding block each implementing the same functionality.

The input interface of the decompanding block is 16 bits.

Figure 7-32 shows a high level block diagram of the decompanding block.

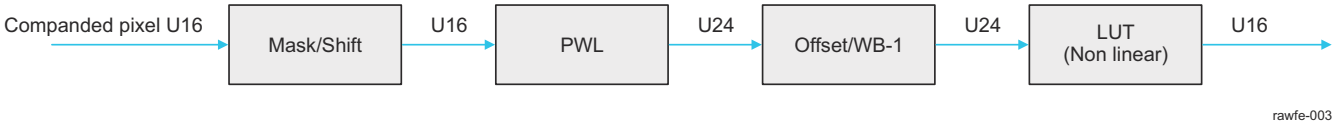

Figure 7-32. RAWFE Decompanding Block Diagram

7.7.3.3.4.1.1 RAWFE Mask & Shift

The mask and shift block is used to mask out any control bits present in the data. The ‘Mask’ is a 16 bit configuration register which will perform a bit wise ‘and’ operation on the incoming data. (For example for sensor data with data in 12 bits and 4 bits of control information, the mask value would be programmed to 0xFFF). The Mask operation is followed by a shift operation. The ‘Shift’ field is a 3 bit configuration register which can perform a right shift (>>) from 0 to 7 bits.

7.7.3.3.4.1.2 RAWFE Piece Wise Linear Operation

The PWL block is used to apply a piece-wise-linear gain on the incoming pixel data and is generally used to uncompress sensor compressed data. The knee points of the PWL curve should be programmed to correspond with the compression knee points used by the sensor configuration.

The PWL block supports an input size from 8 – 16 bits and can support an output up to 24 bits.

Figure 7-33 depicts a PWL curve applied on incoming data

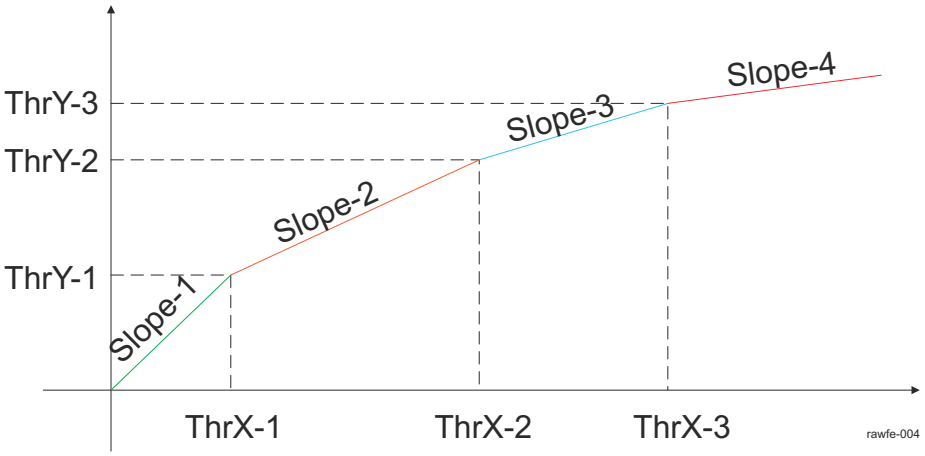

Figure 7-33. RAWFE PWL Curve implementation

Copyright © 2026 Texas Instruments Incorporated

The PWL block implements the following equation assuming the input lies in the nth segment.

$$Out_Pixel = ((X - ThrX_n) \times Slope) + ThrY_n \quad (2)$$

The figure below shows the PWL block architecture

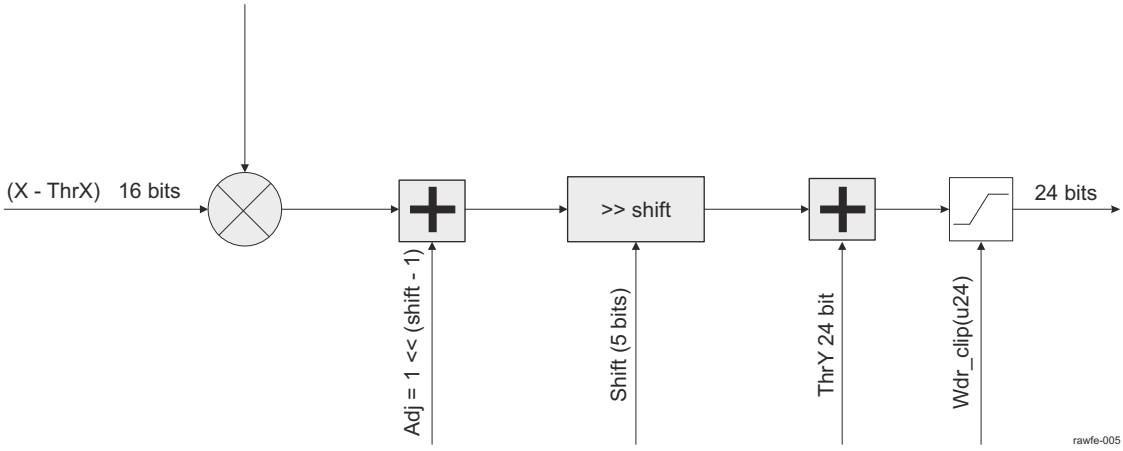

Figure 7-34. RAWFE PWL Block Diagram

The Wdr_clip parameter can be set to clip the output at the desired bit width (typically 20 bits).

7.7.3.3.4.1.3 RAWFE Offset/WB-1 Block

This block is used for applying White balance correction in linear domain as well as for subtracting the DC offset using the signed 24 bit offsets. The functionality is similar to the WB2 block. Note, there is a tap out point to H3A after the offset application, but prior to the gain block. This allows the H3A to receive DC subtracted (but not WB corrected) data.

7.7.3.3.4.1.4 RAWFE LUT Based compression

The LUT based compression is used for addressing multiple use cases.

- The primary function of the LUT is to take the PWL decompounded data (up to 24 bits and after DC subtraction) and compress it using an x^n curve to a bitwidth of 16 bits. This is required since the downstream path is only capable of supporting up to 16 bits of data.
- It can be used to decompand data when the compression curve cannot be addressed using 3 knee points or if the compression is true curve instead of PWL. In this scenario the DC subtraction IP is disabled and the LUT is used to implement both the decompression as well as the DC subtraction functionality.

The LUT compression is modified from the implementation in previous generation ISPs. The previous LUTs had 512 entries leading to a step size of 2^20/512 = 2048. As such there were only 2 LUT points in the critical low range (0-4095) of the image. The LUT implementation is optimized for a 20-bit decompounded data and allows for a step size of 32 in the critical range (lower 12 bits) and a step size of 2048 in the successive ranges.

The Non Linear LUT implementation supports 3 zones for the input range

- For bitWidth < 12 bits, the LUT offers a linear range with a step size of 32. (Only the first 128 locations (plus 129th location for supporting interpolation) are utilized in this mode
- For bitWidths between 13 and 20: This is the most common operating zone for the LUT. In this mode, the range between 0 and 4k is split in 128 locations with a step size of 32. Beyond 4k range, the step is variable and is set to 2k for the highest bit width of 20 and subsequently reduces by half as the bitwidth is reduced (E.g. 1k for 19 bits etc)
- For bitwidths between 21 and 24: In this operation zone, the first 128 locations are used with a varying step size based on bit width such that the step size is 64 for 21 bits of data and doubles with increase in bitWidth.

Copyright © 2026 Texas Instruments Incorporated

(E.g. 128 for 22 bits etc). The remaining locations implement a varying step size between 4k (for 21 bits) and 32k (for 24 bits).

- Example-1: Bitwidth=21 bits:
  - Range 0-8k-> Step size = 64;
  - Range 8k- 2^21 -> Step Size = 4096
- Example-2: Bitwidth = 22 bits
  - Range 0 -16k -> Step Size = 128
  - Range 16k – 2^22 -> Step_Size = 8192
- Example 3: Bitwidth = 24 bits
  - Range 0 – 64K -> Step Size = 512
  - Range 64K - 2^24 -> Step Size = 32k

The LUT logic provides a generic table which can support any bit width and can be used in different regions in the RAWFE as well as other modules.

The LUT3 supports shadowing for very short frame only. If the MMR shadow enable is set then the LUT2 is used on the LUT3 data.

7.7.3.3.4.2 RAWFE WDR Merge Block

The merge block supports merging up to 3 exposures to generate a cumulative 20 bit frame.

The merge block is based on 2 instances of the Motion-Adaptive merge block, each of which is independently capable of supporting the merging of 2 exposures (10 – 16 bits each) to a combined bit width of up to 20 bits. In a more generic scenario the merge block should be designed and verified to support the following scenarios

- Merge 2 exposures of 10 bits each to 16 bits
- Merge 2 exposures of 12 bits each to 16 bits
- Merge 2 exposures of 12 bits each to 20 bits
- Merge 2 exposures (12 bit and 16 bit) to 20 bits.
- Merge 2 exposures of 16 bit each to 20 bits.

Using two instances of the motion adaptive merge block provides the functionality to merge up to 3 independent exposures, each of 12 bits, to a combined bitwidth of 20 bits. The block also provides capability to only merge 2 exposures using a combination of mux and clipping blocks.

The merge block comprises of two instances of the motion adaptive merge (MA1/MA2) as well as an LUT based companding block and mux structures to enable different data flow. To keep the design complexity under control some restrictions are applied to the data connectivity on the merge blocks. A key restriction is that for the two exposure merge only the MA-2 block should be used and the MA-2 should be used along with MA-1 for 3 exposure merge. Further the position of the long and short exposures on each block are fixed. Table 7-95 summarizes some of the possible combinations which can be realized using the logic. (Note, this is not an exhaustive list from a DV perspective).

The MA block when set to bypass/disabled mode, will pass the input stream marked as ‘short’ (refer to Figure 7-30) to the output.

Table 7-95. Figure 7:RAWFE Different merge modes

Merge Mode	MA-1	MA-2		LUT
2 Exposures (12 bit) to 20 bit	Bypassed	Merge Long / Short	Use VS and Short Exposures	Set to 20-16
2 Exposures (12 bit) to 16 bit	Bypassed	Merge Long /Short	Use VS and Short Exposures	Bypassed
2 Exposures (12 bit) to 16 bit with tone mapping	Bypassed	Merge Long /Short	Use VS and Short Exposures	Set to 16-16 mode
2 Exposures (12 & 16) to 20 bit	Bypassed	Merge Long /Short	Use VS and Short Exposures	Set to 20-16
3 Exposures (12 bit each) to 20 bit	Merge Long and Short	Merge VS / MA-1 output	Use all 3 exposures	Set to 20-16
Single exposure companded	Bypass	Bypass	Use VS exposure only	Bypassed

7.7.3.3.4.2.1 RAWFE WDR Motion Adaptive Merge (MA1 / MA2)

This section provides the detailed description of the two instances of the motion adaptive merge.

Figure 7-35 shows the high level block diagram of the MA merge block

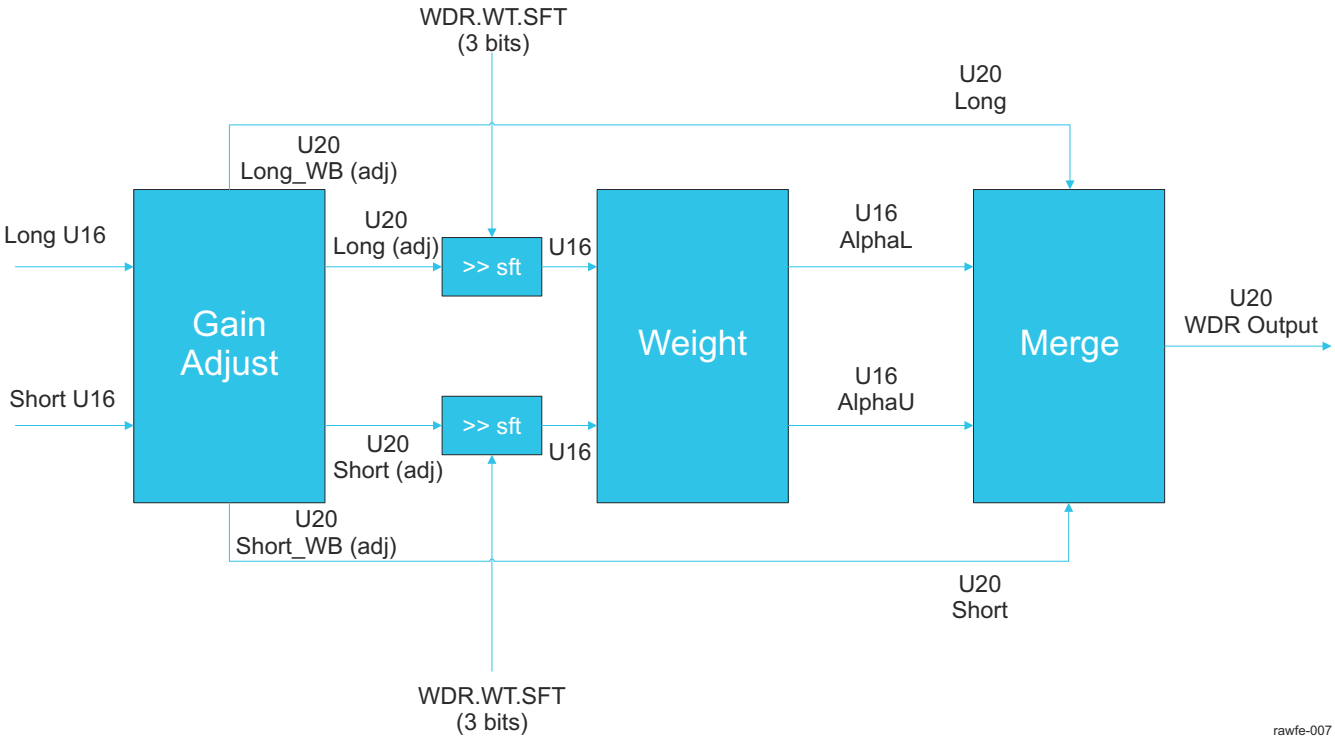

Figure 7-35. RAWFE WDR Motion Adaptive Merge

The MA block receives two inputs each of which can be up to 16 bits. As mentioned earlier, the ordering of the long and the short exposure cannot be changed and should be positioned as it's depicted in the figure above. The MA block consists of 3 main sub-blocks, which are described in the following sub-sections.

7.7.3.3.4.2.2 RAWFE Companding LUT

The companding LUT is used to perform a global tone mapping on the image and reduce the bit depth from 20 bits down to 16 bits. The LUT is implemented as a non uniformly spaced memory, with higher precision in the lower range of the image intensity. The LUT architecture is similar to that used for the decompanding LUT in the previous section.

7.7.3.3.4.3 RAWFE Defective Pixel Correction (DPC) Block for 2x2 Bayer CFA

The defect pixel correction (DPC) block is responsible for correcting defective pixels present on the sensor as an artifact of the manufacturing process. The defect pixel detection can either be LUT based or on the fly (OTF – DPC). For LUT based DPC, the defect map is stored in a memory.

Figure 7-36 shows a high level block diagram of the DPC module. The DPC comprises of two different methods of performing the functionality, each of which is highlighted below. The LUT based defect correction mechanism requires the sensor to be calibrated and the defect positioned stored in memory, whereas the Adaptive DPC automatically detects defects and corrects them. If required the LUT DPC and adaptive DPC can be enabled together in sequence.

Copyright © 2026 Texas Instruments Incorporated

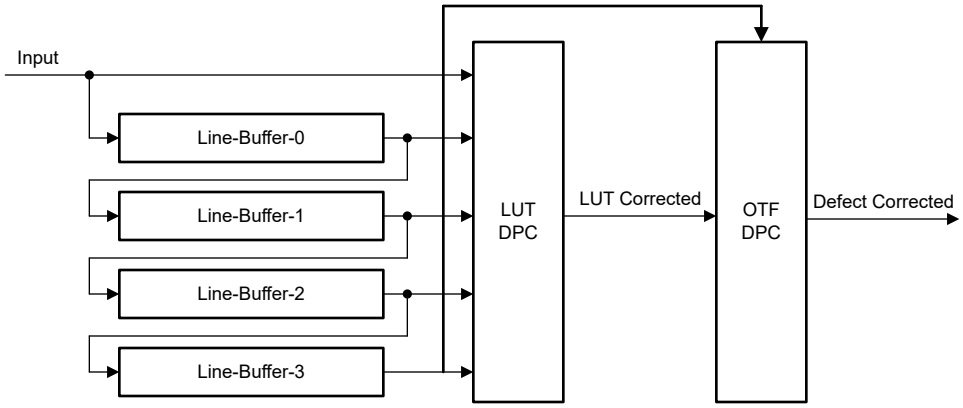

Figure 7-36. RAWFE DPC Block Diagram

7.7.3.3.4.3.1 RAWFE LUT Based DPC

LUT based defect pixel correction provides the highest level of accuracy since all defects can be identified perfectly without any false positives. The LUT based DPC mechanism however suffers from the limitation that the sensor has to be calibrated (each sample has to be individually calibrated) and that can add cost to the testing and qualification process. Some automotive grade sensor vendors provide the defect pixel locations already in an on chip memory and that can additionally be utilized to program the defect LUT without adding the cost. The LUT size for the DPC is constrained to 256 entries, since it is assume for a sensor of 2 -3 Mpix resolution, 256 entries are more than sufficient. Each entry in the LUT is 29 bits with 13 bits for x coordinate, 13 bits for Y coordinate and 3 bits for the method. Figure 7-37 illustrates the organization of the LUT memory

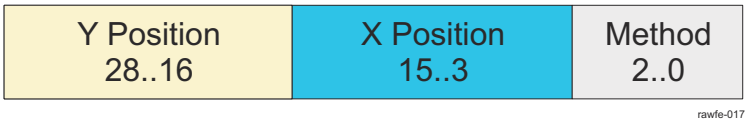

Figure 7-37. RAWFE DPC LUT Memory Organization

A sample table is provided below for 7 entries. The LUT is specified in left to right and top to down fashion (Raster Scan order). As such design only has to look at the current LUT pointer to be able to determine if the current location is a defect or not.

Table 7-96. Figure 14: RAWFE Sample DPC Table

10	1400	0
236	1107	1
236	1200	1
488	10	1
488	100	2
800	138	3
900	1000	1
900	1100	3

The method filed pertains to how the defect pixel is treated once it has been detected. Several possibilities arise including copying from one of the neighbors or using an average of the neighbors. The table below summarizes different methods that can be programmed for treating defect pixels.

Table 7-97. Figure 15:RAWFE LUT DPC Method(s)

Method Value	Functional equivalent
0	Replace with Black or white dot based on config

Copyright © 2026 Texas Instruments Incorporated

Table 7-97. Figure 15:RAWFE LUT DPC Method(s) (continued)

Method Value	Functional equivalent
1	Dout = d4
2	Dout = d5
3	Dout = (d4 + d5)/2
4	Dout = (d2 + d7)/2
5	Dout = d2
6	Dout = d7
7	Dout = ((d2 + d7)/2 + (d4 + d5)/2)/2

The pixel arrangement and numbering convention is depicted in the image below with ‘d0’ being considered the center pixel.

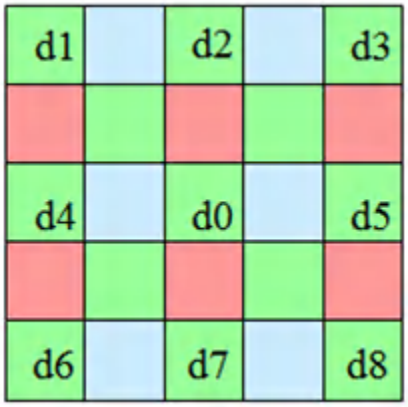

Figure 7-38. RAWFE DPC Pixel numbering convention

When the DPC method is set to ‘0’, the output is either a black or a white pixel (depending on a separate configuration register). With this method, the LUT dpc can be used in conjunction with OTF DPC in a way that the LUT programmed defects are almost always identified by the adaptive DPC. This can be used to accurately correct for all known defects and then using adaptive DPC to correct for temperature or other operating condition based defects. (Defect pixels are strongly correlated with analog gain).

7.7.3.3.4.3.2 RAWFE On-The-Fly (OTF) DPC

The LUT based DPC suffers from the drawback that each sensor die has to be calibrated for defects. The calibration process adds cost to the sensor dies, as such the preferred DPC method relies on automatically detecting the defects based on thresholds.

The OTF DPC algorithm detects defective pixels by comparing the current pixel (d0 on the left of the figure below) against its 8 neighboring pixels with the same color (d1 ~ d8 on the left of the figure below). Let’s use dmax and dmin to denote the maximum and minimum of d1 ~ d8 respectively. If the current pixel d0 is greater than the sum of dmax and a detection threshold T (i.e., d0 > dmax + T) as shown on the right of the figure below, then the current pixel is considered a defect and its value is replaced by dmax. Similarly, if d0 < dmin – T, then the current pixel is replaced by dmin.

Copyright © 2026 Texas Instruments Incorporated

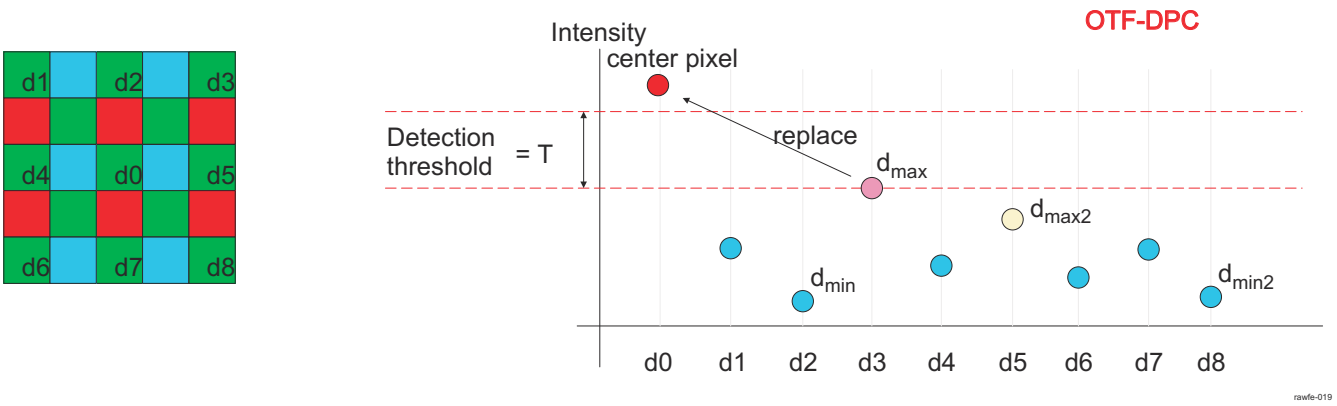

Figure 7-39. RAWFE OTF DPC

The detection threshold T is made adaptive by calculating the local image intensity and using a programmable look-up-table. The local intensity is approximated by the average of the second largest and the second smallest pixel values among d1 ~ d8 (dmax2 and dmin2 respectively in the figure above). With this average value, the threshold T is obtained from the look-up-table with linear interpolation. The look-up-table contains the detection thresholds (U16) at the average values of 0, 512, 1024, 2048, 4096, 8192, 16384, 32768 and the corresponding slope values (S12Q8) for linear interpolation.

7.7.3.3.4.4 RAWFE Defective Pixel Correction (DPC) for 4x4 RGBIR CFA

The DPC algorithm uses the same color neighbors to detect and correct the pixel that is in concern. The 4x4 RGBIR censor data has lower density in red and blue pixels. A larger neighborhood (9x9 pixels) is used to extract 8 same color pixels (d1 to d8) for defective pixel detection and correction for the center pixel d0. The 8 pixels provide the vertical, horizontal, and two diagonal directional neighbors to the center pixel d0.

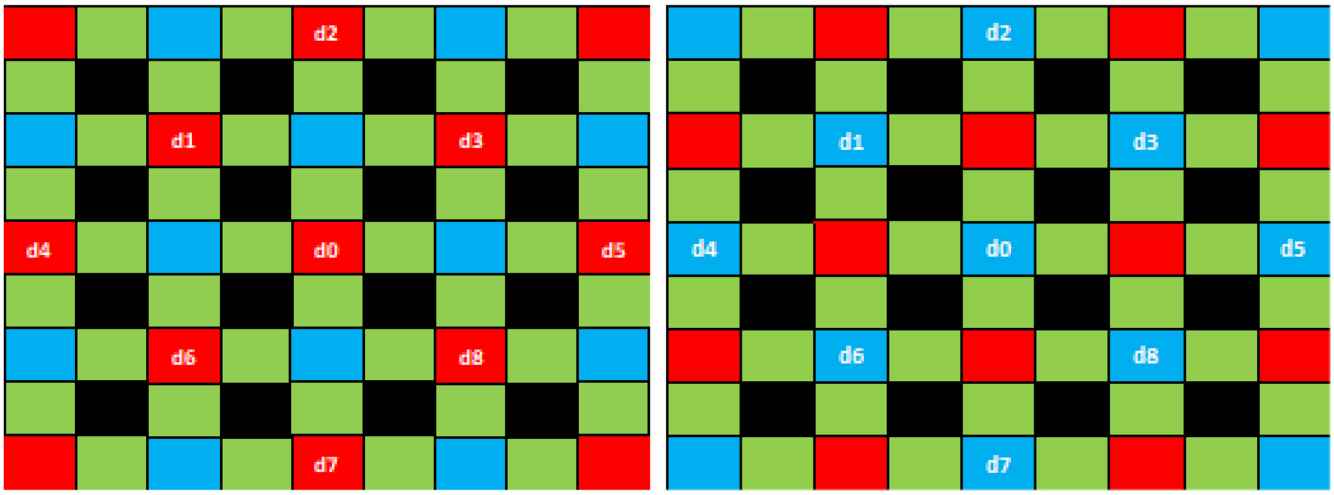

Figure 7-40. Pixels Used in Detecting and Correcting Red and Blue Pixels

Figure 7-40 shows the 8 pixel neighbors (d1 to d8) used to detect and correct center pixel d0 for red and blue pixels. For green and IR pixels, the 8 neighbor pixels are selected in the same way as 2x2 Bayer.

A programmable x-position parameter is added to the threshold and slop LUT to add flexibility in define the piece-wise linear detection threshold curve. The LUT now has 8 entries, each consisting a x-position of threshold curve, a threshold at x-position and a slop at which the threshold changes.

The 2nd LUT, LUT2, is added to allow different color channels to use different threshold curves. For a given color channel, which LUT to use is configured by LUT_MAP register. Since the position of a color channel is

Copyright © 2026 Texas Instruments Incorporated

depending on the pixel color phase in a 4x2 pixel array, OTF DPC uses CFA_PHASE register to determine the pixel positions for a given color channel.

A DPC_COUNT register is used to count the number of detected defective pixels. The count is reset to 0 when a frame starts. It is incremented by one every time when a defective pixel is detected and saturated to 65535.

In OTF DPC, a defective pixel stats memory of 2048 entries is added to record the defective a pixle's x- and y-positions. When enabled, the first 1024 detected defective pixel location is written to the lower 1024 or higher 1024 entries, depending on the configuration. SW can configure OTFDPC_EN_STATS_CFG to update lower or higher stats memory in alternative frames, leaving a whole frame time for SW to read the DPC stats. The defective pixels stats memory is also available in the enhanced 2x2 Bayer mode. The x- and y- positions are organized as in the table below.

Y Position	X Position
25...13	12...0

7.7.3.3.4.5 RAWFE Lens Shading Correction (LSC) and Digital Gain (DG) Block

The lens shading module corrects for the lens fall of (loss of light) at the corners of the lens. Figure 7-41 shows a sample image of this phenomenon and the corresponding result after treating with LSC operation.

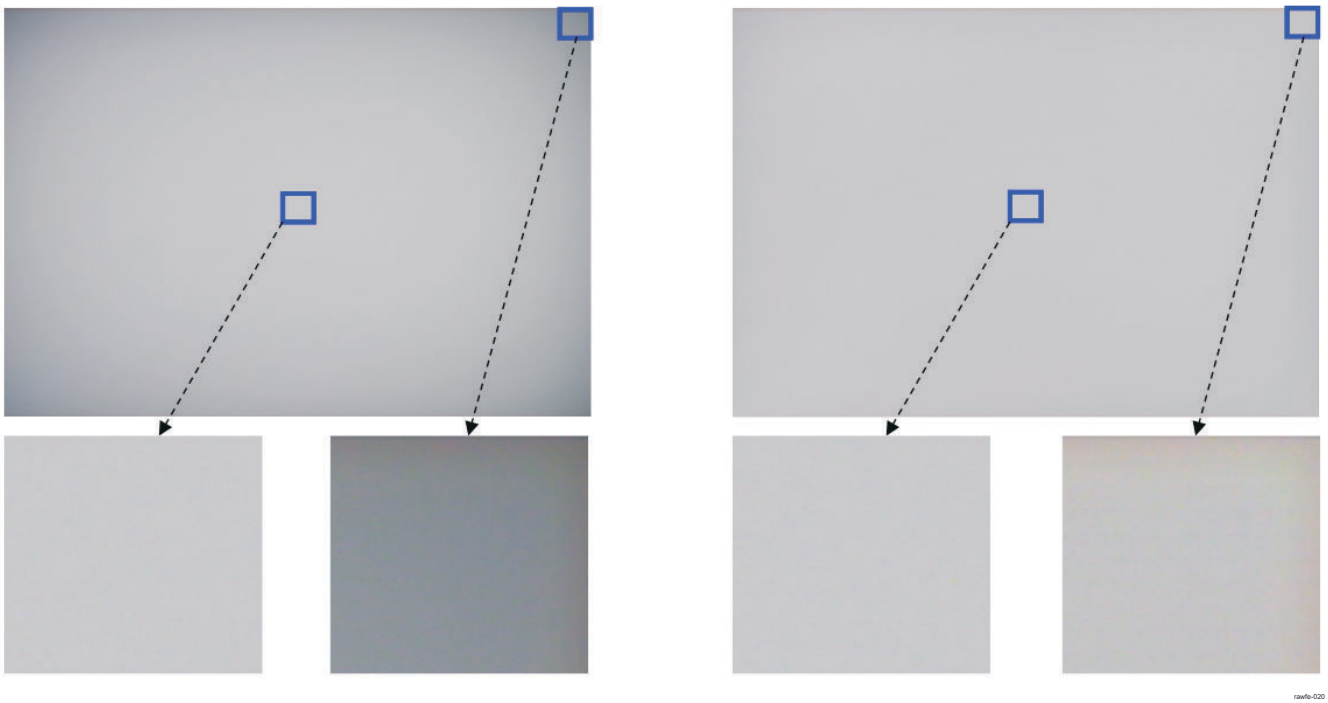

Figure 7-41. RAWFE Before and After LSC

The image on the left shows a block at the center of the lens and a corresponding block at the edge of the lens. Both blocks are equally illuminated, as such should appear equally bright on the image. However, due to lens fall off, the block at the edge appears significantly darker than the block at the center. The image on the right shows the corresponding result after LSC gains have been applied.

This block (2D-LSC) contains lens shading correction by multiplying an image with a gain factor 2-D map, pixel by pixel. The image is conceived to be in Bayer CFA format having a 2x2 color pattern or 4x4 RGBIR pattern. The gain factor map is stored in internal MEMORY down-sampled, and is accessed and up-sampled by the LSC module to pixel resolution before being applied to the pixel data. The key difference from previous generation LSC is that the gain map is stored internally in the memory instead of relying on DRAM fetch.

Copyright © 2026 Texas Instruments Incorporated

The LSC module does not implement any Region of Interest (ROI) functionality and the LSC gain mask is applied on the entire image. Further, only an 8 bit gain is stored in the mask. The gain can be stored in different formats depending on the range. The 8 bits of gain can be used to represent different ranges based on the lsccfg.GAIN_FORMAT register as per the table below

- 0 : U8Q8 -> 0 to 0.996
- 1 : U8Q8 +1 -> 1 to 1.996
- 2 : U8Q7 -> 0 to 1.992
- 3 : U8Q7 +1 -> 1 to 2.992
- 4 : U8Q6 -> 0 to 2.984
- 5 : U8Q6 +1 -> 1 to 3.984
- 6 : U8Q5 -> 0 to 6.968
- 7 : U8Q5 +1 -> 1 to 7.968

Note

The offset field is removed from the implementation of the LUT and only the gain field is retained. This is different than previous implementations.

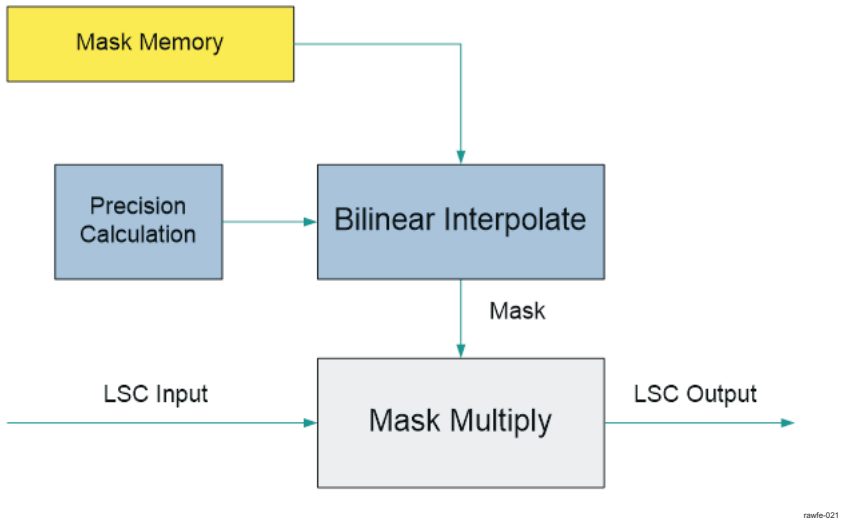

Figure 7-42. RAWFE LSC block diagram

7.7.3.3.4.5.1 RAWFE LSC Features Supported

- Gain map is MxN down-sampled, M being the horizontal sampling factor, N being the vertical sampling factor, M and N being {8,16,32.64,128} independently. For a given frame size, choice of M and N has to be made to ensure the entire LSC LUT to fit into LSC LUT memory.
- The size of the internal memory is based on a 5Mpix sensor (2592x1944) with 32x64 downscaling ratio. As such the size is approximately 20,832 bytes (5248 locations with 4 Bytes/location)
- Every two locations are used to store the channel gains for 8 color channels. Alternatively, the memory can be programmed to support 4 color channels with each location storing channel gains for 4 color channel, Table 4 lists a few example M and N configurations for either 8 or 4 color channels. Note that supporting 8 color channels is only for LSC_CH_MODE = 2.
- Support 8-bit entry in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0 to shift the range up)

7.7.3.3.4.5.2 RAWFE LSC Image Framing with Respect to Gain Map Samples

The gain maps are stored MxN downsampled, and needs to be upsampled by LSC hardware before being applied to the image. It is most straightforward for LSC hardware if the gain map grid is aligned with the input

Copyright © 2026 Texas Instruments Incorporated

image grid. In other words, first pixel corresponds to a source gain map entry, rather than being upsampled through interpolation. Figure 7-43 shows the LSC active region with respect to the gain map grid.

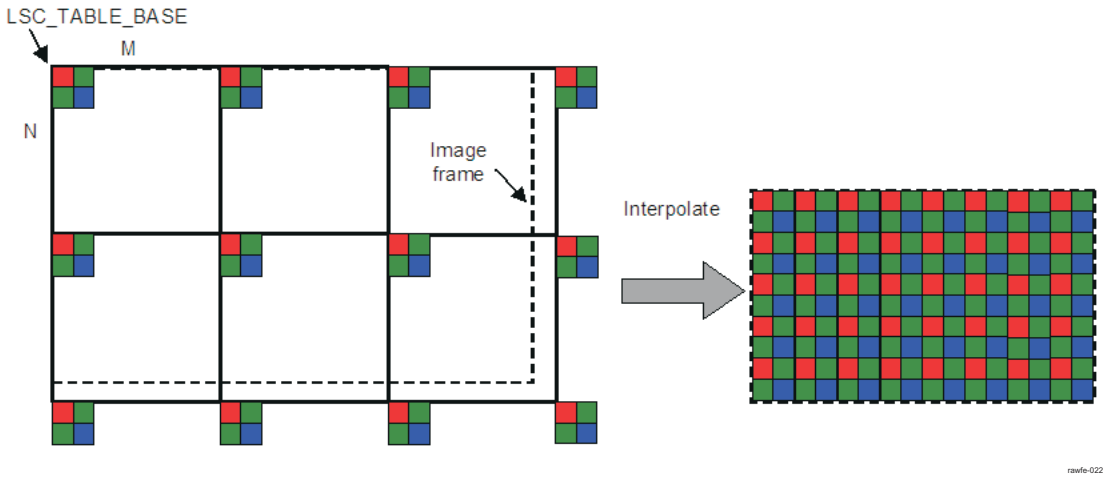

Figure 7-43. RAWFE LSC Active Region with Respect to Gain Map Samples

Figure 7-43 illustrates the LSC active region and map up-scaling feature. (The maps are stored independently per color channel)

For an image frame size of W x H (output and input are the same size), gain map being MxN downsampled, it needs (ceil(W / M) +1) x (ceil(H / N) +1) x 4 bytes of gain map data in internal memory. (NOTE: ceil() represents the ceiling function).

The LSC module is designed to work with Bayer CFA data, having R/Gr/Gb/B color pattern or RGBIR pattern with up to 16 color channels. For the purpose of functional description for Bayer CFA, it is assumed that Red is the starting color, but any other starting color or other 2x2 color pattern can be used by placing color gains in the appropriate order.

Each 2x2 set of samples is stored together in a 32-bit word in internal memory. For R/Gr/Gb/B CFA data and 8x8 downsampled gains, the following order is assumed in the gain map, using conventional (X, Y) coordinate notation (X for horizontal offset and Y for vertical offset):

Line 0: R(0,0) Gr(1,0) Gb(0,1) B(1,1) R(8,0) Gr(9,0) Gb(8,1) B(9,1)...

Line 1: R(0,8) Gr(1,8) Gb(0,9) B(1,9) R(8,8) Gr(9,8) Gb(8,9) B(9,9)...

7.7.3.3.4.5.3 RAWFE LSC Gain Map Upsampling in 2x2 Mode (LSC CHN_MODE = 0)

Before applying to pixel data, the gain maps are upsampled to pixel resolution via bilinear interpolation.

Note that the LSC operation is neutral to color pattern. The starting color of the gain map should be consistent with the starting color of the image, and can be any color. The hardware upsamples each phase of the gain map as a separate plane, and applies the upsampled gain map to the image with the same color phasing.

Upsampling of the pixel-by-pixel gains is performed by locating the 4 same-color anchors for each destination gain value, and applying bilinear interpolation. Gain for a red pixel at destination coordinate (x, y), relative to the starting pixel of the image, is computed as described below.

Let the 4 anchors for a red gain output be denoted by R00, R01, R10, and R11, and the destination coordinate is (k, l) with respect to R00, the red gain is interpolated as:

$$R\left(x,y\right) = \frac{R00 \times (M-k) \times (N-l) + R01 \times k \times (N-l) + R10 \times (M-k) \times l + R11 \times k \times l}{MN} \quad (3)$$

Where:

Copyright © 2026 Texas Instruments Incorporated

- k = x mod M
- l = y mod N
- i = | x / M | × M
- j = | y / N | × N
- R00 = R(i, j)
- R01 = R(i+M, j)
- R10 = R(i, j+1)
- R11 = R(i+M, j+N)

Similarly for the other colors the formulas are:

$$GR\left(x,y\right) = \frac{GR00 \times (M-k) \times (N-l) + GR01 \times k \times (N-l) + GR10 \times (M-k) \times l + GR11 \times k \times l}{MN} \quad (4)$$

$$GB\left(x,y\right) = \frac{GB00 \times (M-k) \times (N-l) + GB01 \times k \times (N-l) + GB10 \times (M-k) \times l + GB11 \times k \times l}{MN} \quad (5)$$

$$B\left(x,y\right) = \frac{B00 \times (M-k) \times (N-l) + B01 \times k \times (N-l) + B10 \times (M-k) \times l + B11 \times k \times l}{MN} \quad (6)$$

In legacy 2x2 mode (LSC_CFG.CHN_MOD register field = 0), however, the relation of (k, l) and (i, j) to (x, y) for other colors is different from the relation for red. For GR, the relations are:

- k = (x-1) mod M
- l = y mod N
- i = | (x-1) / M | × M + 1
- j = | y / N | × N
- GR00 = GR(i, j)
- GR01 = GR(i+M, j)
- GR10 = GR(i, j+N)
- GR11 = GR(i+M, j+N)

In legacy 2x2 mode, the number of supported color channels is fixed at 4.

7.7.3.3.4.5.4 RAWFE LSC Gain Map Upsampling in 4x4 Color Mapping Mode (LSC CNH_MODE = 1 or 2)

In both of the modes, mapping 4x4 color channels to up to 4 or 8 channel gains is configured by the LSC_LUT_MAP07 and LSC_LUT_MAP815 registers. The 16-channel LSC_LUT_MAP is enumerated spatially, independent of the actual pixel color, in each 4x4 CFA as shown in Figure 7-44.

0	1	2	3
4	5	6	7
8	9	10	11
12	13	14	15

Figure 7-44. Channel Indexing in 4x4 Pixel Pattern

The mapping is intended for 4x4 RGBIR support. However, it can also be used in 2x2 Bayer sensors by repeating the 2x2 pattern 4 times (2 horizentally and 2 vertically) to form 4x4 pattern and applying 16 LSC_LUT_MAP for corresponding16 pixels to 4 or 8 channel gains in the LUT.

When LSC_CFG.CHN_MODE register field = 1, 4-channel gain is supported. All the channel mapping has to point to gain 0-gain3. When CHN_MODE = 2, 8-channel gain is supported. All the 8 channel gains may be

Copyright © 2026 Texas Instruments Incorporated

used across frames. Alternative, the 8 gains may be configured to a dual 4 channel gain groups (gain0-3 and gain4-7), allowing re-programming of 4 gains for next frame while other 4 gains are used for the current frame. This feature could be useful for multiple sensor support where different sensors may need different gains for shading correction.

Upsampling of the pixel-by-pixel gains is performed by locating the 4 same color channel anchors for each pixel gain value, and applying bilinear interpolation. Let the 4 anchors for a channel gain output be denoted by CH00, CH01, CH10, and CH11, and the pixel coordinate is (k, l) with respect to CH00. Gain for a pixel channel at destination coordinate (x, y), relative to the anchor points, is computed as:

$$\mathrm{CH}\left(\mathrm{x},\mathrm{y}\right) = \frac{\mathrm{CH00} \times (\mathrm{M}-\mathrm{k}) \times (\mathrm{N}-\mathrm{l}) + \mathrm{CH01} \times \mathrm{k} \times (\mathrm{N}-\mathrm{l}) + \mathrm{CH10} \times (\mathrm{M}-\mathrm{k}) \times \mathrm{l} + \mathrm{CH11} \times \mathrm{k} \times \mathrm{l}}{\mathrm{MN}} \quad (7)$$

Where:

- k = x mod M
- l = y mod N
- i = | x / M | × M
- j = | y / N | × N
- R00 = CH(i, j)
- R01 = CH(i+M, j)
- R10 = CH(i, j+1)
- R11 = CH(i+M, j+N)

7.7.3.3.4.6 RAWFE Gain & Offset Block

The gain block allow 2 primary functions

- Allow for digital gain to be applied if the image is too dark even after analog gain and exposure time have been set to the maximum
- Independent gain setting for each color channel in 13 bit format U13Q9 with 9 bits of fraction.
  - Allows a gain value from 0 to 31.996 in steps of 1/256.

The Gain block can be configured to apply an offset on top of the gain. This is to support the log compressed image mode, where in the traditional WB Gain becomes an offset.

7.7.3.3.4.7 RAWFE H3A

7.7.3.3.4.7.1 RAWFE H3A Overview

The H3A module supports the control loops for autofocus, auto white balance, and auto exposure by collecting statistics about the raw image. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus (AF) engine:

  The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a 2D block of data referred to as a paxel. The AF engine supports the following features:
  - Peak mode in a paxel: Accumulation of the maximum focus value (FV) of each line in a paxel
  - Accumulation mode in a paxel
  - Accumulation of horizontal and vertical focus value in a paxel
  - Up to 12 paxels in the horizontal direction and up to 12 paxels in the vertical direction with vertical focus
  - Up to 36 paxels in the horizontal direction and up to 128 paxels in the vertical direction with horizontal focus only
  - Programmable width and height for the paxel/window
  - Programmable red, green, and blue position within a 2 × 2 matrix
  - Separate horizontal start for paxel and filtering
  - Programmable vertical and horizontal line increments within a paxel

Copyright © 2026 Texas Instruments Incorporated

  - Horizontal FV uses parallel infinite impulse response (IIR) filters configured in a dual-biquad configuration with individual coefficients (two filters with 11 coefficients each). The filters are intended to compute the sharpness/peaks in the frame on which to focus.
  - Vertical FV uses a 5-tap FIR filter with 8-bit coefficients. With horizontal steps each paxel has up to 32 columns to be maintained for vertical FV calculation.
- Auto exposure and auto white balance (AE/AWB) engine:

  The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the 2D block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:
  - Accumulate clipped pixels along with all nonsaturated pixels in each window per color
  - Accumulate the sum of squared pixels in each window per color
  - Minimum and maximum pixel values in each window per color
  - Support for up to 36 horizontal windows with sum + { sum_sq or min+max} output
  - Support for up to 56 horizontal windows with sum output
  - Support for up to 128 vertical windows
  - Programmable width and height for the windows. All windows in the frame are the same size.
  - Separate vertical start coordinate and height for a black row of paxels that is different than the remaining color paxels
  - Programmable horizontal sampling points in a window
  - Programmable vertical sampling points in a window
- Double-buffer for paxel/window accumulation
- H3A data path is 10 bits.
- Maximum input size is 4096 pixels.

7.7.3.3.4.7.2 RAWFE H3A Top-Level Block Diagram

The block diagram in Figure 7-45 shows the process of the AF and AE/AWB data paths through the H3A module.

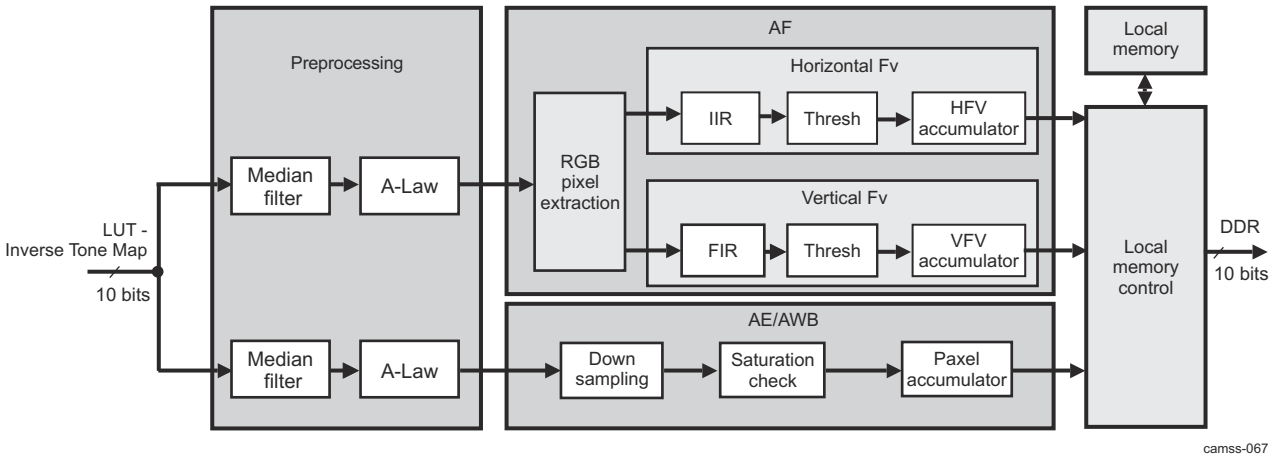

Figure 7-45. RAWFE H3A Top-Level Block Diagram

7.7.3.3.4.7.3 RAWFE H3A Line Framing Logic

In certain cases the number of clock cycles between HD pulses is greater than the line buffer included in the H3A. To solve this problem a framing module was added before the line buffer. The framing module uses the VISS_RAWFE_H3A_LINE_START register to find the position of the first pixel to place into the line buffer. All other registers reference this point as the 0 pixel for their start positions. The line size is 4096 pixels. After 4096 clock cycles the framing logic disables the line buffer and waits until the next HD. If the next HD comes before 4096 clock cycles, then the active region ends immediately and the counter waits

Copyright © 2026 Texas Instruments Incorporated

for the VISS_RAWFE_H3A_LINE_START register count to be reached again. For the vertical position the VISS_RAWFE_H3A_LINE_START[31:16] SLV bit field can be used to determine where the start point of the frame is relative to the rising edge of VD. This logic allows for an active frame to cross VD boundaries and remain in the same frame.

Figure 7-46 shows the RAWFE H3A frame format settings.

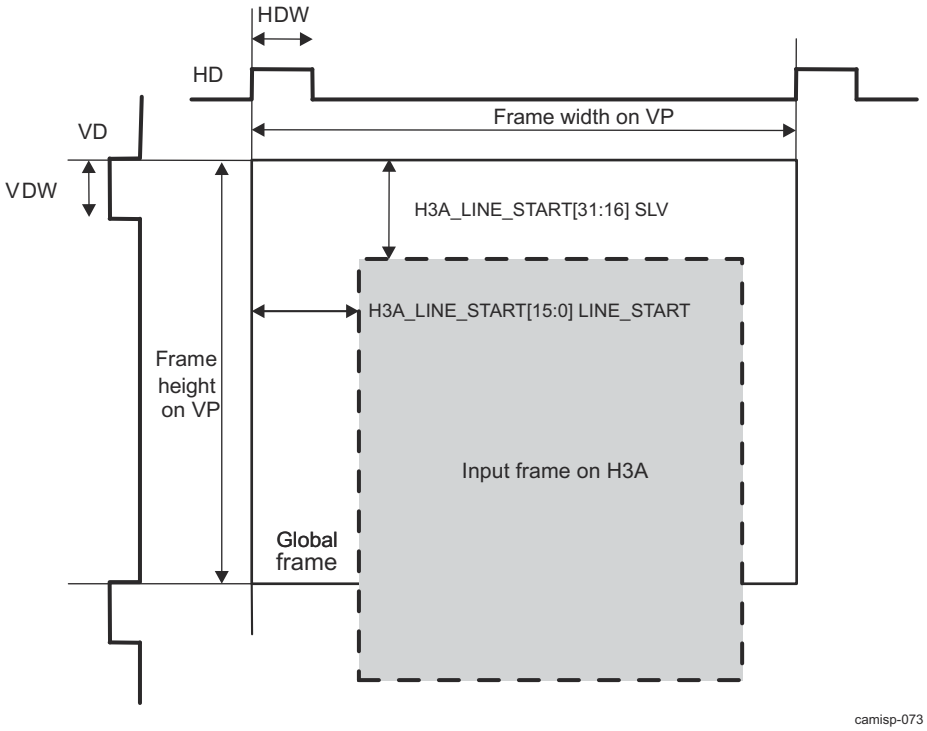

Figure 7-46. RAWFE H3A Frame Format Settings

Note

(Frame width on VP) - (VISS_RAWFE_H3A_LINE_START[15:0] LINE_START) must be less than or equal to 4096, because the H3A memory lines are limited to 4096 pixels.

7.7.3.3.4.7.4 RAWFE H3A Optional Preprocessing

The input to the H3A module is 10-bit RAW data from the IPIPEIF. A 10-bit to 8-bit A-Law compression step can be enabled and disabled separately for the AF engine (the VISS_RAWFE_H3A_PCR[1] AF_ALAW_EN bit) and the AE/AWB engine (the VISS_RAWFE_H3A_PCR[17] AEW_ALAW_EN bit). A-Law compression offers added protection against overflowing the accumulators.

If the A-Law table is enabled, the output is 10 bits, with the upper two bits filled with 0.

For the AF process, a horizontal median filter can be enabled and disabled (the VISS_RAWFE_H3A_PCR[2] AF_MED_EN bit) before A-Law compression. This filter is useful for reducing temperature-induced noise. The horizontal median filter calculates the absolute difference between the current pixel (i) and pixel (i – 2), and between the current pixel (i) and pixel (i + 2). If the absolute difference exceeds a threshold, and the sign of the differences is the same, the average of pixel (i – 2) and pixel (i + 2) replaces pixel (i). The threshold of the horizontal median filter can be set in the VISS_RAWFE_H3A_PCR[10:3] MED_TH bit field.

7.7.3.3.4.7.5 RAWFE H3A Autofocus Engine

The AF engine works by extracting each green (Gr or Gb) pixel from the video stream and subtracts a fixed offset of 128 or 512 (depending of whether A-Law is enabled or disabled) from the pixel value. The offset value

Copyright © 2026 Texas Instruments Incorporated

is then passed through an IIR filter and the absolute value of the filter output is the focus value (FV). Both FV and FV^2 are produced. The FV and FV^2 values can be accumulated or the maximum for each line/column can be accumulated. The following sections describe this process in more detail.

7.7.3.3.4.7.5.1 RAWFE H3A Paxel Extraction

From the paxel starting coordinate (the VISS_RAWFE_H3A_AFPAXSTART[27:16] PAXSH and VISS_RAWFE_H3A_AFPAXSTART[11:0] PAXSV bit fields) specifies the starting point of the paxel grid, with respect to first pixel of the input image frame.

The paxel starting coordinate also indicates which color pixels are extracted if VF is enabled (that is, if VISS_RAWFE_H3A_PCR[20] AF_VF_EN = 1). Normally, either Gr or Gb is used for AF, but it is not important to the hardware whether it is red, green, or blue. If VF is not enabled, then the red, green, and blue pixel extraction is controlled by the VISS_RAWFE_H3A_PCR[13:11] RGBPOS bit field to extract the correct colors from the input stream. Figure 7-47 shows the available options for this bit field. The red and blue pixel positions are interchangeable. For each 2 × 2 grid, the green pixels are summed to create a single value. Because of this, the amplitude of the green output contains 2 pixels, while the red and blue outputs each contain 1 pixel.

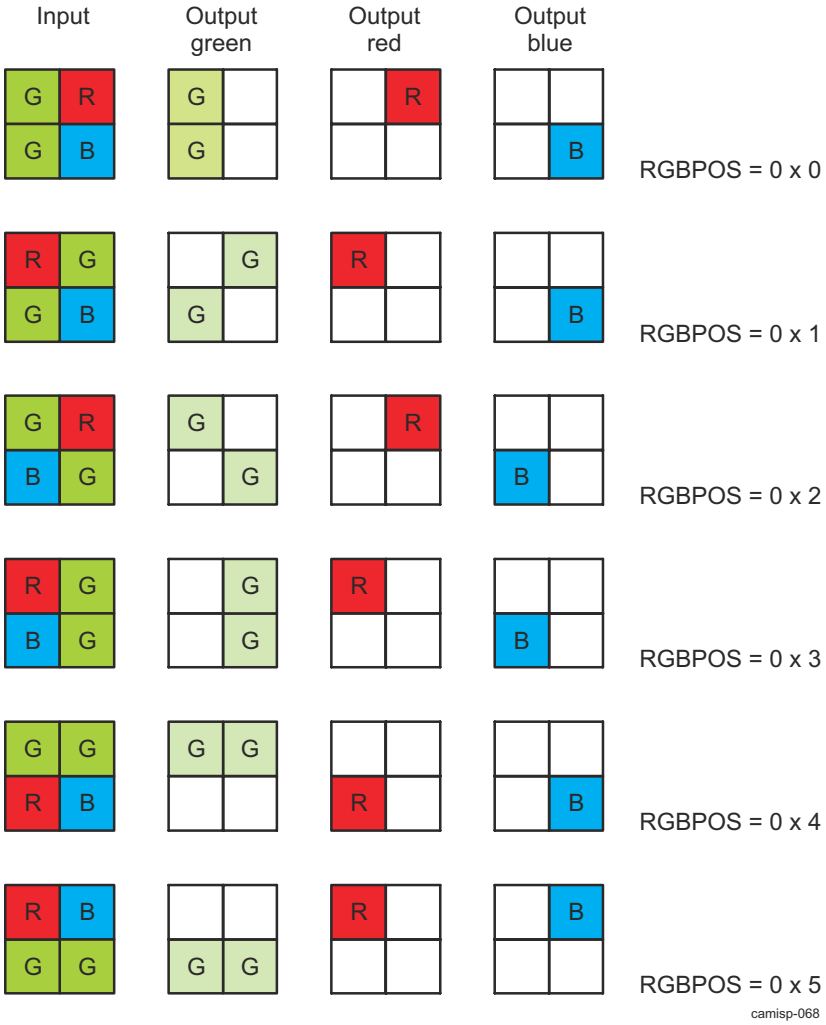

Figure 7-47. RAWFE H3A Red, Green, and Blue Pixel Extraction Examples

Each paxel is VISS_RAWFE_H3A_AFPAX1[23:16] PAXW × VISS_RAWFE_H3A_AFPAX1[7:0] PAXH (width × height) pixels. Inside each paxel, horizontal FV can skip lines, operating on one every VISS_RAWFE_H3A_AFPAX2[16:13] AFINCV lines. Vertical FV can skip columns, operating on one every

Copyright © 2026 Texas Instruments Incorporated

VISS_RAWFE_H3A_AFPAX2[20:17] AFINCH columns. Up to 32 columns are supported for each paxel. If floor (PAXW/AFINCH) >= 32, only the first 32 designated columns are operated on. Because PAXW, PAXH, AFINCV, and AFINCH are all even numbers, AF always operates on the same green color, Gr or Gb. IIR filters for the horizontal FVs start operation at column VISS_RAWFE_H3A_AFIIRSH[11:0] IIRSH.

Figure 7-48 shows the RAWFE H3A horizontal/vertical fv paxel configuration.

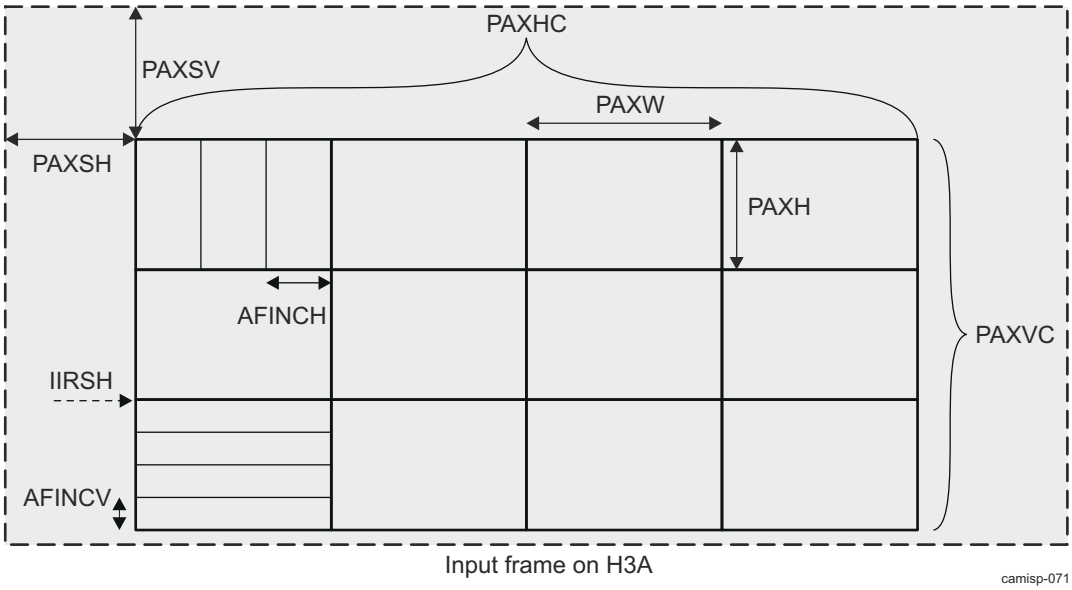

Figure 7-48. RAWFE H3A Horizontal/Vertical FV Paxel Configuration

Note

(VISS_RAWFE_H3A_AFPAXSTART[27:16] PAXSH) + (VISS_RAWFE_H3A_AFPAX2[5:0] PAXHC) × (VISS_RAWFE_H3A_AFPAX1[23:16] PAXW) <= [(Frame width on VP) – (VISS_RAWFE_H3A_LINE_START[15:0] LINE_START)] <= 4096

Table 7-98 lists the bit fields that configure the size and number of paxels.

Table 7-98. RAWFE H3A Paxel Register Field Descriptions

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AFPAX1[23:16] PAXW	8	Paxel width (in pixels)
VISS_RAWFE_H3A_AFPAX1[7:0] PAXH	8	Paxel height (in lines)
VISS_RAWFE_H3A_AFPAX2[5:0] PAXHC	6	Paxel count for horizontal direction
VISS_RAWFE_H3A_AFPAX2[12:6] PAXVC	7	Paxel count for vertical direction
VISS_RAWFE_H3A_AFPAX2[16:13] AFINCV	4	Line increments in a paxel
VISS_RAWFE_H3A_AFPAX2[20:17] AFINCH	4	Column increments in a paxel
VISS_RAWFE_H3A_AFPAXSTART[27:16] PAXSH	12	Paxel start position H
VISS_RAWFE_H3A_AFPAXSTART[11:0] PAXSV	12	Paxel start position V
VISS_RAWFE_H3A_AFIIRSH[11:0] IIRSH	12	IIR filter start position

The H3A AF engine also has an option for an advanced or normal stats collection mode. When 0xCA00 is written to the VISS_RAWFE_H3A_ADVANCED[31:15] ID bit field, then VISS_RAWFE_H3A_ADVANCED[0] AF_MODE can be used to toggle between normal and advanced AF stats collection mode. When the advanced AF stats collection mode is enabled, the ZEROS section of the AF paxel packet is filled with the sum of the maximum FVs, regardless of the color, from HFV_1 and HFV_2.

Copyright © 2026 Texas Instruments Incorporated

7.7.3.3.4.7.5.2 RAWFE H3A Horizontal FV Calculator

The FV calculator takes the unsigned red/green/blue extracted data and subtracts 128 or 512 (depending on whether A-Law is enabled) to place the data in the range –128 to 127 or –512 to 511.

After removing the offset, the data is sent through two parallel IIR filters configured in a dual-biquad configuration. Each filter uses a unique set of 11 programmable coefficients. Each coefficient is 12-bits-wide with 6 bits of decimal, S12Q6 (VISS_RAWFE_H3A_AFCOEF010 to VISS_RAWFE_H3A_AFCOEF0010 for SET0, and VISS_RAWFE_H3A_AFCOEF110 to VISS_RAWFE_H3A_AFCOEF1010 for SET1). The filter-shift registers are cleared on each horizontal line at the position set by the register IIR horizontal start register (the VISS_RAWFE_H3A_AFIIRSH[11:0] IIRSH bit field). The absolute values of the output (16 bits wide with 4 bits of decimal, U16Q4) of both filters are then sent to the AF accumulator module. Signed clipping is performed during the FV calculation. If the input value is m bits (signed) and the required output value is n bits, clipping transforms the input to between -2^1 and 2^1. Values lower than -2^1 are set to -2^1, and values higher than 2^1 are set to 2^1.

7.7.3.3.4.7.5.3 RAWFE H3A HFV Accumulator

The horizontal focus value (HFV) accumulator takes the output of the horizontal IIR filter and accumulates values for each paxel. The size and number of paxels is configurable by registers.

Table 7-98 lists the register fields that configure the size and number of paxels:

- In peak mode (VISS_RAWFE_H3A_PCR[14] FVMODE = 0x1), the maximum value is accumulated.
- In sum mode (VISS_RAWFE_H3A_PCR[14] FVMODE = 0x0), all HFV_n are accumulated in a paxel.

The following equations detail the calculation for:

- Sum of pixel values used in HFV: The pixel values that are used for filtering and accumulation of HFV are also accumulated in this sum of pixel values.
- HFV_n (HFV_n_peak for peak mode or HFV_n_sum for sum mode)
- HFV_count_n
- HFV_sq_n (HFV_sq_n_peak for peak mode or HFV_sq_n_sum for sum mode)

n = 1 or 2 for IIR1 and IIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
for (k=0; k<PAXH) // Loop on paxel rows
{
 rowpeak_n = 0;
 for (l=0; l<PAXW; l++) // Loop on values within a row
 {
 aIIRout_n = ABS(IIRout_n);
 if (aIIRout_n >= threshold_n)
 {
 hfval = aIIRout_n - threshold_n;
 HFV_count_n++;
 }
 else hfval = 0;
 if (hfval > rowpeak_n)
 {
 rowpeak_n = HFV_n;
 }
 HFV_n_sum += hfval;
 HFV_sq_n_sum += (hfval* hfval + RNDADD) >> RNDSHIFT;
 } // Finished looping on values in a row
 HFV_n_peak += rowpeak_n;
 HFV_sq_n_peak += (rowpeak_n * rowpeak_n + RNDADD) >> RNDSHIFT;
}
```

- threshold_n is VISS_RAWFE_H3A_HVF_THR[15:0] HTHR1 and VISS_RAWFE_H3A_HVF_THR[31:16] HTHR2, respectively.
- IIRout_n is the IIRout_1 and IIRout_2 outputs, respectively.
- HFV_count_n and HFV_sq_n are not sent to the DMA interface if VF is disabled.
- RNDADD and RNDSHIFT depend on whether input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.

Copyright © 2026 Texas Instruments Incorporated

- If VF is enabled, only the green color channel values are output to the DMA interface.
- In sum mode:
  - HFV_n = HFV_n_sum
  - HFV_sq_n = HFV_sq_n_sum
- In peak mode:
  - HFV_n = HFV_n_peak
  - HFV_sq_n = HFV_sq_n_peak

7.7.3.3.4.7.5.4 RAWFE H3A VFV Calculator

The VFV calculator takes the unsigned extracted data through two FIR filters, each with a set of five coefficients (VCOEF1_x, where x = 0 to 4, in the VISS_RAWFE_H3A_VFV_CFG1 and VISS_RAWFE_H3A_VFV_CFG2 registers for FIR 1, and VCOEF2_x, where x = 0 to 4, in the VISS_RAWFE_H3A_VFV_CFG3 and VISS_RAWFE_H3A_VFV_CFG4 registers). Each coefficient is 8 bits wide with 4 bits of decimal (S8Q4). The filter outcome is downshifted by 4 bits and takes an absolute value to produce a 16-bit unsigned value. This is then sent to threshold VISS_RAWFE_H3A_VFV_CFG2[31:16] VTHR1 for FIR 1, and VISS_RAWFE_H3A_VFV_CFG4[31:16] VTHR2 for FIR 2, and square logic to produce VFV_n and VFV_sq_n.

7.7.3.3.4.7.5.5 RAWFE H3A VFV Accumulator

The VFV accumulator takes the output of the vertical FIR filters and accumulates values for each paxel. The size and number of paxels is configurable by registers.

Table 7-98 lists the bitfields that configure the size and number of paxels.

The following equations detail the calculation for:

- VFV_n
- VFV_count_n
- VFV_sq_n

n = 1 or 2 for FIR1 and FIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
FIR_coef_n = [VCOEFn_0, VCOEFn_1, VCOEFn_2, VCOEFn_3, VCOEFn_4]; /* coefficient values in S8.4
format */
aFIRout_n = (ABS(inner_product(extracted_G, FIR_coef_n)) + 8) >> 4;
if (aFIRout_n >= threshold_n)
{
 VFV_n = aFIRout_n - threshold_n
 VFV_count_n++;
}
else VFV_n = 0;
VFV_sq_n = (VFV_n * VFV_n + RNDADD) >> RNDSHIFT;
```

- threshold_n is VISS_RAWFE_H3A_VFV_CFG2[31:16] VTHR1 and VISS_RAWFE_H3A_VFV_CFG4[31:16] VTHR2, respectively.
- FIRout_n is the FIRout_1 and FIRout_2 outputs, respectively.
- RNDADD and RNDSHIFT depend on whether the input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.

7.7.3.3.4.7.6 RAWFE H3A AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows, and then subsamples each window into 2 × 2 blocks. For each subsampled 2 × 2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2 × 2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

The AE/AWB module has three output format modes, which are set through the VISS_RAWFE_H3A_AEWCFG[9:8] AEFMT bit field:

- Sum of square mode: VISS_RAWFE_H3A_AEWCFG[9:8] AEFMT = 0x0

Copyright © 2026 Texas Instruments Incorporated

- Min/max mode: VISS_RAWFE_H3A_AEWCFG[9:8] AEFMT = 0x1
- Sum-only mode: VISS_RAWFE_H3A_AEWCFG[9:8] AEFMT = 0x2

7.7.3.3.4.7.6.1 RAWFE H3A Subsampler

The subsampler partitions the frame into windows using the size, count, and starting location parameters shown on the left in Figure 7-49. Each window is further sampled down to a set of 2 × 2 blocks. The horizontal and vertical distances between the start of blocks within a window is programmable using the parameters shown on the right in Figure 7-49.

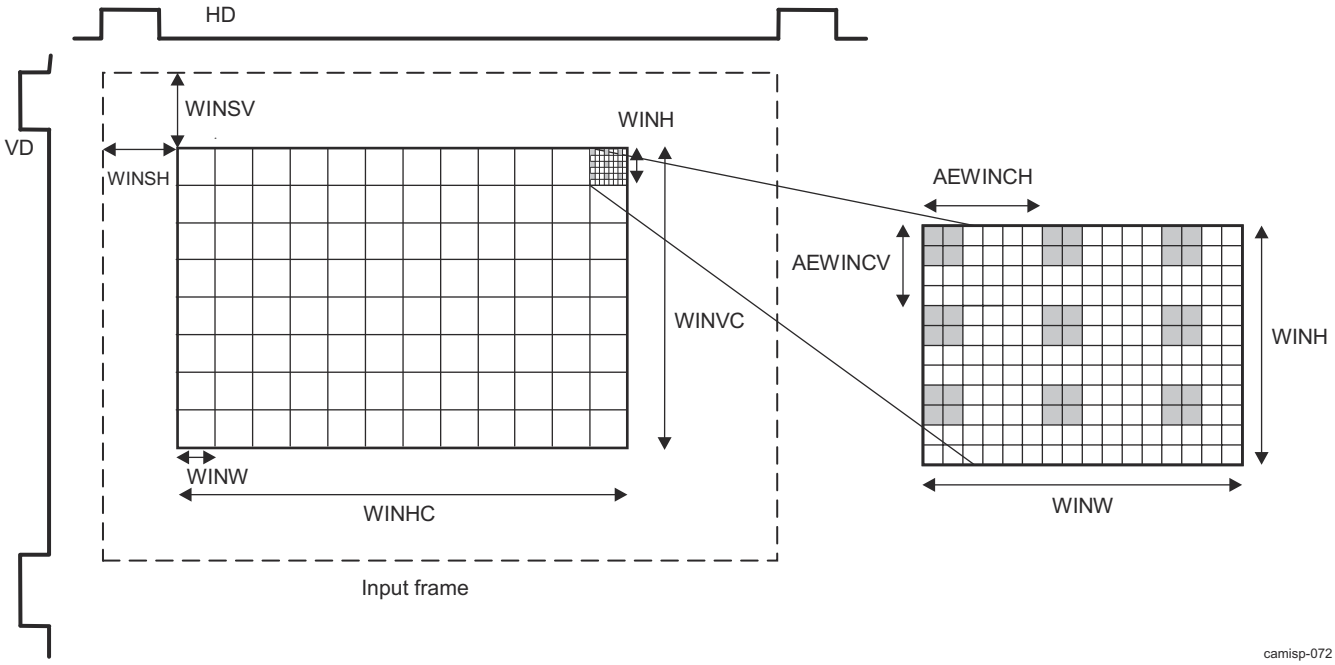

Figure 7-49. RAWFE H3A AE/AWB Window Configurations

Table 7-99 lists the bit fields that configure the window and block sizes, counts, and starting positions.

Table 7-99. RAWFE H3A AE/AWB Window Register Field Descriptions

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
VISS_RAWFE_H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
VISS_RAWFE_H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
VISS_RAWFE_H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
VISS_RAWFE_H3A_AEWINSTART[11:0] WINSH	12	Window start position H
VISS_RAWFE_H3A_AEWINSTART[27:16] WINSV	12	Window start position V
VISS_RAWFE_H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
VISS_RAWFE_H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples

7.7.3.3.4.7.6.2 RAWFE H3A Additional Black Row of AE/AWB Windows

In addition to the 128 rows of windows, the AE/AWB module provides support for an additional row of windows for black data. This data may be useful in determining the DC offset noise of the rest of the data. The black row of windows can be before or after the regular rows of windows. The vertical start line for the black row of windows is specified in the VISS_RAWFE_H3A_AEWINBLK[27:16] WINSV bit field, and the height is specified in the VISS_RAWFE_H3A_AEWINBLK[6:0] WINH bit field. The horizontal starting pixel and horizontal width of the black row of windows are the same as for the regular rows of windows.

Figure 7-50 shows a black row of windows before rows of windows.

Copyright © 2026 Texas Instruments Incorporated

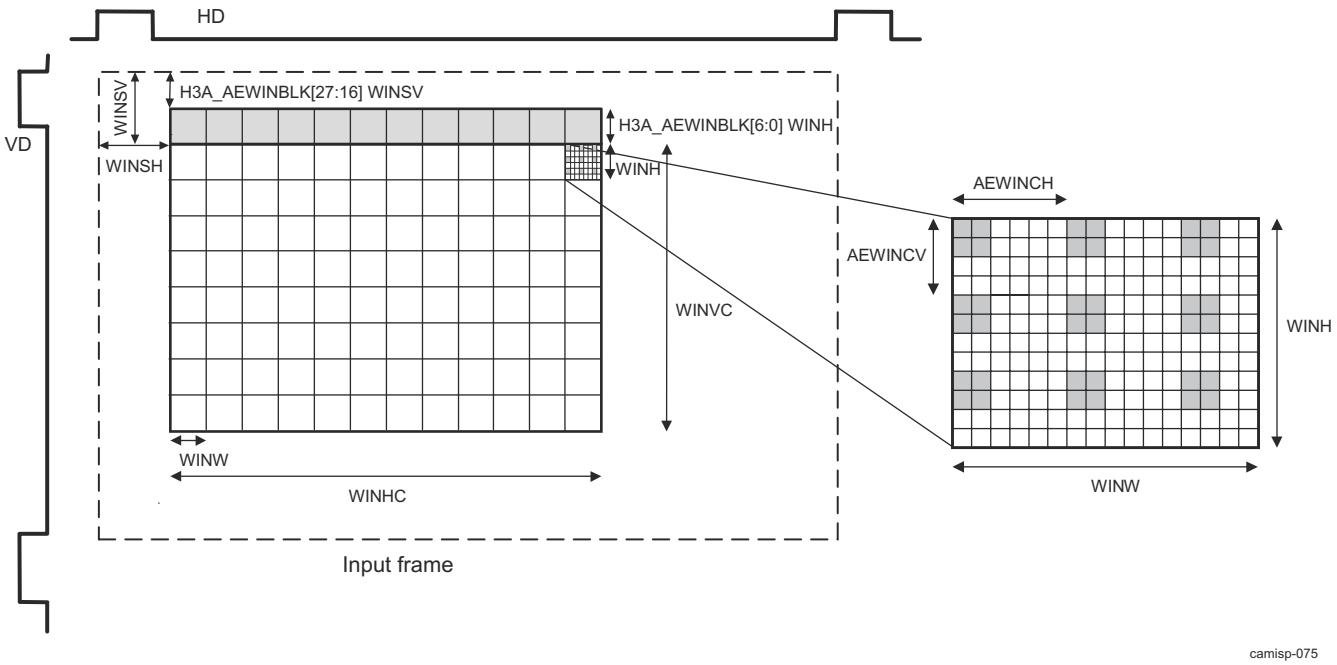

Figure 7-50. RAWFE H3A Black Row of Windows Before Regular Rows of Windows

Table 7-100 lists the bit fields that configure the window and block sizes, counts, and starting positions.

Table 7-100. RAWFE H3A AE/AWB Window With Additional Black Row Register Field Descriptions

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
VISS_RAWFE_H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
VISS_RAWFE_H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
VISS_RAWFE_H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
VISS_RAWFE_H3A_AEWINSTART[11:0] WINSH	12	Window start position H
VISS_RAWFE_H3A_AEWINSTART[27:16] WINSV	12	Window start position V
VISS_RAWFE_H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
VISS_RAWFE_H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples
VISS_RAWFE_H3A_AEWINBLK[27:16] WINSV	12	Window start position H for single black line
VISS_RAWFE_H3A_AEWINBLK[6:0] WINH	7	Window height (in lines) for single black line

7.7.3.3.4.7.6.3 RAWFE H3A Saturation Check

The saturation check module compares the data from the subsampler to the value programmed in the VISS_RAWFE_H3A_PCR[31:22] AVE2LMT bit field. This value is the maximum clipping value. If all 4 pixels in the 2 × 2 block are less than the AVE2LMT value, the value of the unsaturated block counter is incremented. There is one unsaturated block counter per window. The unsaturated block counters are later written to memory.

7.7.3.3.4.7.6.4 RAWFE H3A AE/AWB Accumulators

The output from the saturation check module and the subsampler module are separately accumulated for each pixel in every 2 × 2 pixel block for each window. Therefore, there are eight accumulators per window (one accumulator for each pixel in a 2 × 2 pixel block, times two sets of accumulators: clipped/saturated data and presaturated data). Each of the 4 pixels in the 2 × 2 pixel grid is associated with a color R, Gr, B, Gb); however, the output of these accumulators is referenced by position in the grid, not color.

Copyright © 2026 Texas Instruments Incorporated

The accumulators are 16 bits wide, and the accumulated data is 10 bits wide. Therefore, when a window contains more than 64 pixels of the same color, an overflow risk exists. This risk can be reduced by enabling the A-Law conversion in the preprocessing stage. See Section 7.7.3.3.4.7.4 for details.

The AE/AWB module has a shift value for the accumulation of pixel values that is set in the VISS_RAWFE_H3A_AEWCFG[3:0] SUMSHFT bit field.

7.7.3.3.4.7.7 RAWFE H3A DMA Interface

The DMA interface module takes the data from the AF engine and AE/AWB engine and builds packets to be sent to the memory through the BL module.

The data interface has separate start pointers for the AF and AE/AWB engines.

- The starting address for the AF engine is the VISS_RAWFE_H3A_AFBUFST[31:5] AFBUFST bit field.
- The starting address for the AE/AWB engine is the VISS_RAWFE_H3A_AFBUFST[31:5] AEWBUFST bit field.

The DMA interface module continuously loops through this data as it builds the packets. To optimize the transfer sizes, the DMA interface sends out an AF or AE transfer for each row of paxels or windows. This requires that each horizontal row of paxels or windows starts and ends on a 32-byte boundary. If a horizontal row of paxels or windows ends on a non-32 byte boundary, the hardware packs zeroes. The counts for the AEW that occur every eight windows is sent in the row with the eighth consecutive window.

Table 7-101 shows the packet formats for AF with vertical AF enabled.

7.7.3.3.4.7.8 RAWFE H3A Events and Status Checking

The AF and AEW engines generate an interrupt event at the end of processing each frame. However, these two interrupts are internally tied together so that only one H3A interrupt signal is generated. If the AF engine and AEW engine do not process the same frame concurrently, this should not be an issue. However, if they do run concurrently, one of two outcomes may occur:

- The H3A interrupt may seem to trigger only once for each frame. This can happen when the processing for the AF and AEW engines finishes at or near the same time. The interrupt service routine (ISR) does not have enough time to clear the interrupt flag for the first interrupt before the second interrupt occurs.
- The H3A interrupt may trigger twice for each frame. This can happen when the AF engine or the AEW engine finishes processing the frame much earlier than the other engine. In this case, the ISR does have enough time to clear the interrupt flag for the first interrupt by the time the second interrupt occurs.

The outcome depends on the difference in location of the last paxel/window in the frame (determines when processing is finished), the frequency of the relative clocks in the system, the occurrence and triggering of other interrupts in the system, and the latencies of the context switching and ISR execution.

The VISS_RAWFE_H3A_PCR[15] BUSYAF and/or VISS_RAWFE_H3A_PCR[18] BUSYAEAWB status bits are set when the start of frame occurs (if the VISS_RAWFE_H3A_PCR[0] AF_EN and/or VISS_RAWFE_H3A_PCR[16] AEW_EN bits are 1 at that time). They are automatically reset to 0 at the end of processing a frame. The VISS_RAWFE_H3A_PCR[15] BUSYAF and/or VISS_RAWFE_H3A_PCR[18] BUSYAEAWB status bits may be polled to determine the end of frame status.

7.7.3.3.4.7.9 RAWFE H3A Interface Mux

The H3A logic also implements an LUT or Shift /clip block. The LUT logic is same as the decompanding LUT in the previous section(s) with some minor modifications. The input bit width to the LUT cannot exceed 16 and the LUT entry size is only 10 bits, since the H3A logic works on 10 bit data.

The logic also implements a shift and clipU10 functionality for converting data from up to 24 bits down to 10. The shift parameter has to be programmed to implement the desired shift value. The shift register programming must ensure that the output of the shift is not greater than 16bits when the LUT is enabled and it should not be greater than 10 bits when the LUT is disabled. In addition to the outputs from the 3 PWL/DC and the LSC output, H3A interface mux can also be fed by PCID Bayer output.

7.7.3.3.4.7.10 RAWFE H3A interface to LSE

The H3A interface to LSE is VBUSP. It uses channel id to indicate data or control information. Please refer to LSE functional spec on control information mapping to channel id bits.

7.7.3.3.4.7.11 RAWFE H3A Erratas

The following hardware restrictions apply and need to be taken care of by software:

1. When AF is enabled software can not use the first or last pixels in the window. Start at position 2 end at line -2.
2. When AEW is enabled software can not use the first pixel in a window. Start at position 2.
3. (PAXW+1) % (AFINCH+1) != 1 when VF enabled (PAXW and AFINCH are raw MMR parameters)

7.7.3.3.5 RAWFE Programmer's Guide

7.7.3.3.5.1 RAWFE Core programming details

There are multiple use cases that can be enabled with this module, however broadly the use case are broken in to two categories, one for Companded Data sensors and the other for Separate Exposures sensors. The following fields should be programmed correctly for the IP to function

- PWL Core
- Set slopes and thresholds as per sensor settings only for Companded sensors
- Decompanding LUT

Copyright © 2026 Texas Instruments Incorporated

- This LUT is used for global tone map of decompounded data from 24 bits to 16 bits. (This is typically not used for separate exposures sensor)

- Merge Logic
- Program the merge block based on the exposure rations of the incoming data.
- This block is typically not used for companed sensors.
- LUT after merge should be programmed to tone map from 20 bits down to 16 (Separate exposure sensors only)

- DPC/ LSC
- Set as per tuning parameters for both companded/separate exposures sensors

- H3A LUT and settings
- Use LUT if H3A input comes after LSC. Program LUT to apply inverse global curve.
- Use shift if data is coming from exposures directly.

7.7.3.3.5.2 RAWFE Initialization Sequence

See Section 7.7.2, *VPAC Subsystem* for details.

7.7.3.3.5.3 RAWFE Real-time Operating Requirements

See Section 7.7.2, *VPAC Subsystem* for details.

7.7.3.4 VISS Pattern Conversion and IR Demosaicing (PCID) Module

7.7.3.4.1 Overview and Feature List

The PCID produces both Bayer and IR data concurrently from input RGBIR image. Bayer channel data is fed to rest of the VISS pipe line and IR channel output is directly written to memory using one of LSE channels. VPORT Delay SYNC_FIFO supports programmable horizontal delay to match the delay with FCP output. Figure 7-51 captures integration of PCID into VISS.

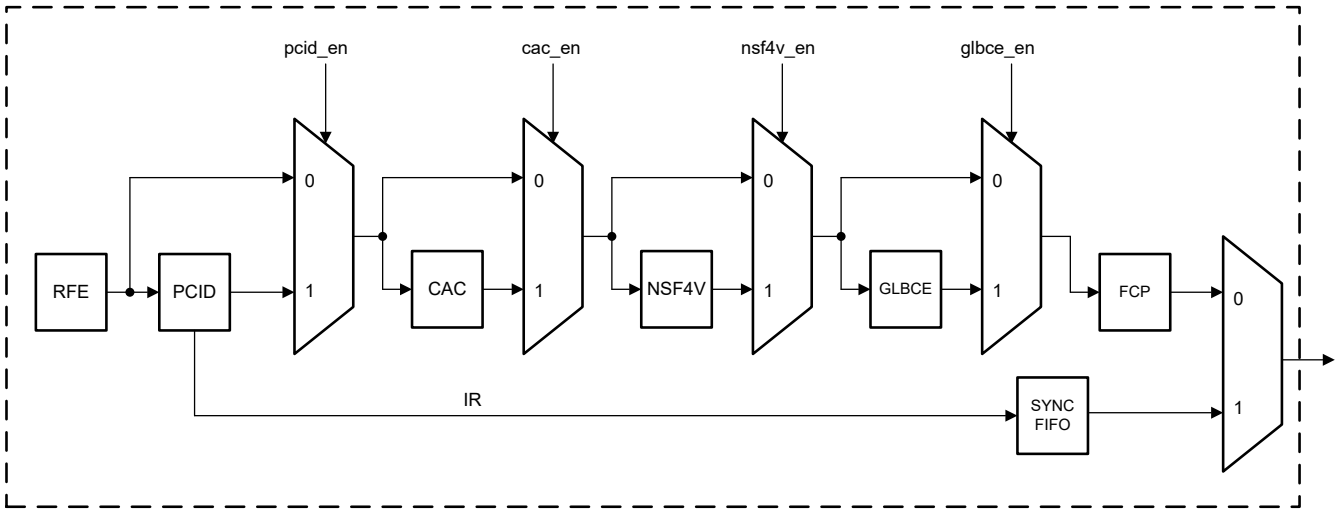

Figure 7-51. PCID Integration in VISS

7.7.3.4.1.1 PCID Features Supported

- Performs pattern conversion on upto 16bits per pixel 4x4 RGBIR sensor data
  - Generates concurrent Bayer and full resolution IR output
  - Supports choice to interpolate the missing R/B pixel values at IR location to create Bayer output
- Can decontaminate Generated Bayer pattern of the IR signal
  - Supports programmable IR subtraction factor value in range [0, 2) for individual color channels

Copyright © 2026 Texas Instruments Incorporated

  - Supports spatial smoothening of the pixel level IR subtraction factors
- Supports 16-bit to upto 16-bit generic Gamma LUT on IR output
- Supports Constant Hue or Color difference method for pattern conversion and IR interpolation

7.7.3.4.2 Functional Operation

The PCID block integrates pattern conversion (re-mosaicing), IR up-sampling and IR subtraction functionality into a single block as illustrated in Figure 7-28. The Pattern conversion and IR up-sampling block performs the task of interpolating missing pixel values, where it uses a two-stage process for re-mosaicing and IR demosaicing.

In the first step, missing green channel information in the input 4x4 RGBIR CFA (at the R, B and IR locations) is interpolated to obtain the green plane to full resolution. In the second step the missing R, B and IR values are interpolated to obtain the re-mosaiced 2x2 Bayer pattern and full resolution IR output. When interpolating the missing pixel values up-sampled green plane acts as a guide for interpolation along the local features such as edges and helps avoid the smoothening. The hardware allows user to choose between constant hue or constant color interpolation schemes along with configurable parameter values that allow precedence for preservation of particular image features during the interpolation process.

The key concerns when subtracting IR signal from the re-mosaiced Bayer pattern are that the level of IR contamination is function of DBF design, the IR contamination of the R, G and B pixels is variable, and subtraction of the IR signal from clipped/saturated pixels can lead to introduction of artifacts. The PCID module can calculates the subtraction factors for every pixel location and used by IR subtraction block for decontamination based on user defined parameters.

7.7.3.4.3 Calculation of pixel level IR subtraction factors

The PCID block enables subtraction of scaled IR signal value from generated 2x2 Bayer CFA pattern as

$$R' = R - Xr \times IR \quad (8)$$

$$G' = G - Xg \times IR \quad (9)$$

$$B' = B - Xb \times IR \quad (10)$$

Where IR subtraction scales {Xr, Xg or Xb } used for a pixels are calculated in a two-step process involving the calculation of pixel level IR subtraction factors and optional spatial smoothening of the calculated IR subtraction factors to suppress noise and obtain smooth transitions.

To avoid subtraction of the IR signal from clipped/saturated pixels and in-turn introduction of color artifacts in the created Bayer pattern, HW allows user to define a cut-off value for R, G and B pixels over which the IR subtraction is disabled. Further to have smoother transition of the IR decontamination scales immediately below the cut-off value HW allows programming of the transition range over which the IR subtraction range gradually increases from no IR subtraction at the cut-off threshold to maximum programmed IR subtraction factor. To enable calculation of IR subtraction factor for Bayer output value at at IR locations in the input CFA (where no R/G/B value is natively available) HW uses nearest maximum R/G/B pixel value for the location to calculate the IR subtraction factor based on this value especially if it is above cut-off or just below it within the transition range. For this user can configure the influence of the nearest maximum R/G/B pixel as function of the L1 distance with values in range [0,1]. When the maximum R/G/B pixel values in a neighborhood are in ranges close to the cut-off value the HW allows user to spatially smoothen the calculated IR subtraction factors in 5x5 region before performing IR subtraction.

Copyright © 2026 Texas Instruments Incorporated

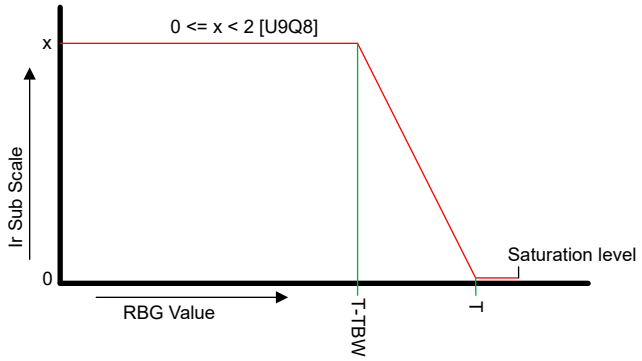

Figure 7-52. Calculated IR Subtraction Scale

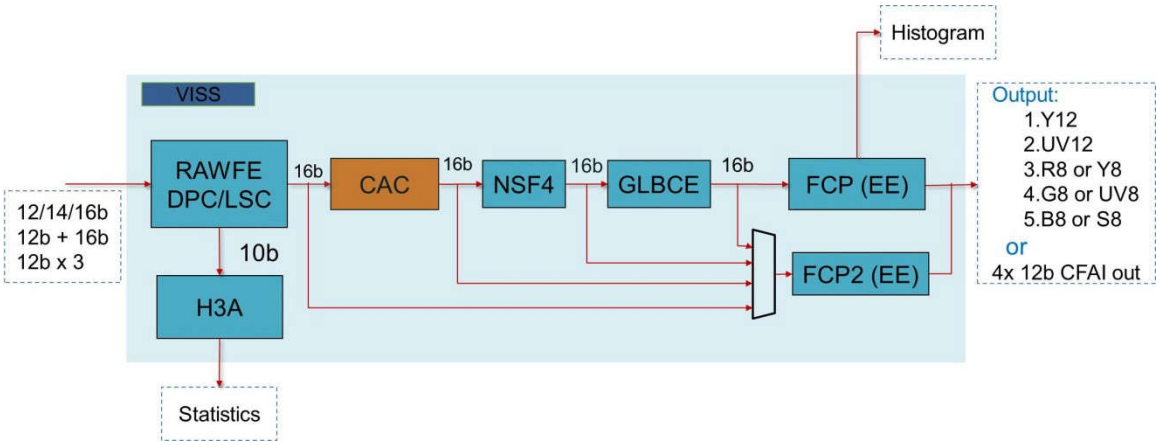
Figure 7-52 shows the calculated IR subtraction scale values with regard to the maximum neighborhood value as a function of user-defined cut-off threshold (T)), transition range TBW and the desired maximum IR subtraction factor for the output Bayer channel.

The PCID block when outputting the interpolated IR image allows user to apply a tone curve on the output to compress the bitdepth from 16bit to 16/12/10/8 bits. The Tone curve can be defined using an IR remap LUT defined using 609 16bit knee points stored in32bit containers.

7.7.3.5 VISS Chromatic Aberration Correction (CAC) Module

7.7.3.5.1 Overview and Feature List



7.7.3.5.1.1 Features Supported

- Chromatic Aberration Correction (CAC) for Red and Green color in Bayer color formats
- Generic mesh based model for CAC
- LUT to store programmable differential correction with 1/8th pixel precision
- Programmable Block size with each block having 2 LUT entries covering entire frame
  - Intermediate correction values are calculated using bilinear interpolation
- Bi-cubic pixel interpolation on corrected back mapped pixel
- Supports Horizontal Correction in the range of -8.0 to +8.0 and Vertical Correction in the range of -4.0 to +4.0
- Performance: up to 1 Pix/cycle (excluding blanking)
- Streaming based processing architecture targeted to integrate with VISS
- Support 16-bit pixel
- Logic support frame dimension of 8Kx8K. Line memory support is limited to 4K line width

7.7.3.5.2 Functional Description

Copyright © 2026 Texas Instruments Incorporated

7.7.3.5.2.1 CAC Integration in VISS

The VISS consist of following hardware accelerators:

- RFE (RAW-FE): The RAW-FRONT HW block does RAW pixel (for example, Bayer, RCCC, RGBW, etc.) processing on captured image data from sensor and pass-on to CAC, NSF4V, GLBCE block, and then to Flexible ColorProc HW block for demosaicing and color conversion.
- CAC (Chromatic Aberration Correction): Captured in this section.
- NSF4V: Spatial Noise filter supporting generic 2x2 pixel format with 16-bit pixel size. NSF4V IP can be bypassed in the applications where visual enhancement is not desired.
- GLBCE: Used for dynamic range control within image for visual quality. If contrast enhancement on input image is required for visual quality RFE/CAC/NSF4V output is processed by GLBCE block. Otherwise GLBCE is bypassed to FCP.
- FCP (FLEXible COLOR PROCessing): The FLEX-COLOR-PROC HW receives data from GLBCE and does demosaincing and color conversion. The output of COLOR-PROC is sent to VPAC shared memory to be written into DDR for rest of vision processing by programmable processors (for example, DSP or Arm) or Vision HW Blocks (for example, VPAC or DMPAC).

7.7.3.5.2.2 Introduction

Chromatic aberration, also known as “color fringing” or “purple fringing”, is a common optical problem that occurs in low quality lens when a lens is either unable to bring all wavelengths of color to the same focal plane (*Longitudinal Chromatic aberration*), and/or when wavelengths of color are focused at different positions in the focal plane (*Lateral Chromatic aberration)* .

Figure 7-53 shows one example of Chromatic Aberration referred as *Lateral Chromatic Aberration* (LCA). In this case, all colors are in focus in the same plane, but the foci are not placed along the optical axis. CAC Hardware accelerator performs *Lateral Chromatic aberration* correction is as part of VISS Pipe line.

7.7.3.5.2.3 Functional Operation

CAC correction requires remapping locations of Red and Blue pixels to align with Green pixel. Green pixel is taken as reference and assumed no correction is needed on Green pixel. CAC HWA is implemented using line based back mapping architecture. Correction involves back-mapping each output pixel to pixel position in the source image, and thus the corrected image is fully populated. As the back mapped pixel locations mostly fall onto fractional coordinates, correction involves bi-cubic interpolation among the nearest available pixels.

As shown in Figure 7-54, CAC consists of Timing control module, 8KB LUT with mesh correction offset table, Mesh LUT bi-linear interpolation block, Pixel interface module, pixel bi-cubic interpolation block and 10 pixel line memories.

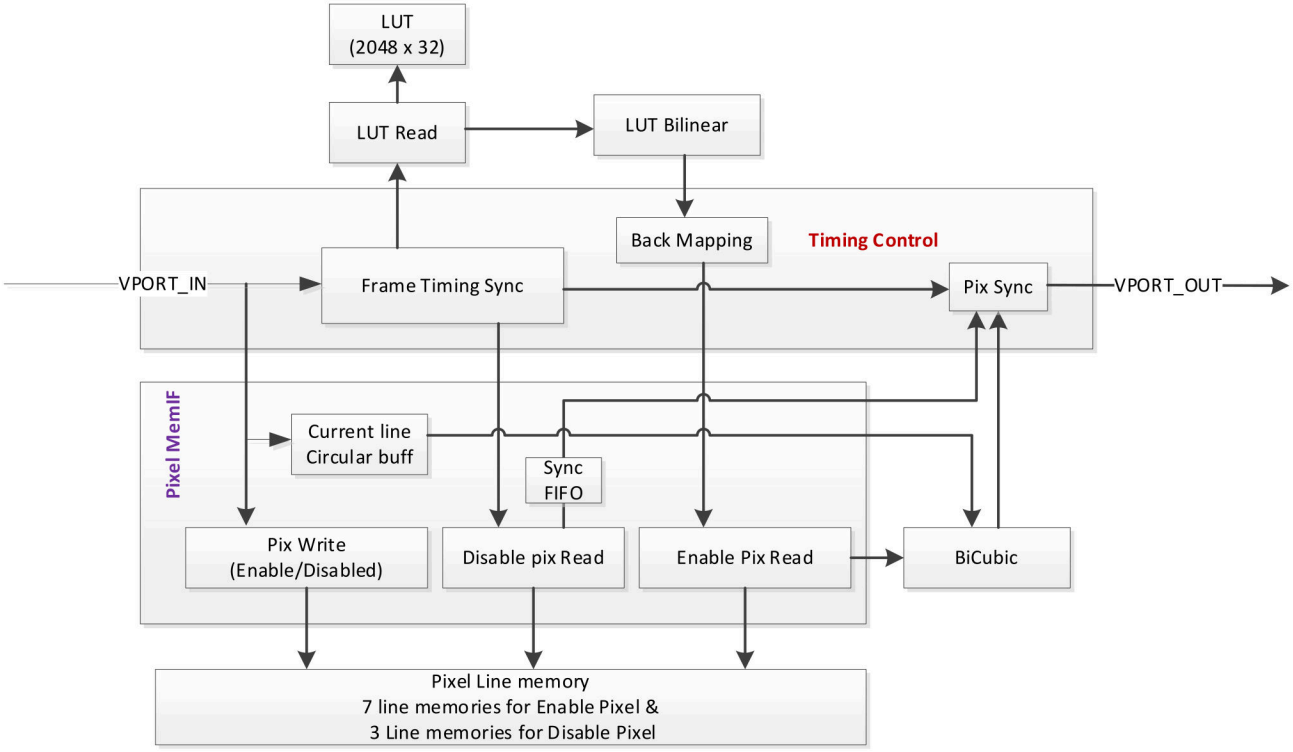

Figure 7-54. CAC Functional Block Diagram

The Timing Control module handles all the timing synchronization aspects of CAC. It generates the Output frame co-ordinates, initiates the Mesh LUT operation on receiving 7th input valid line. It also handles timing synchronization between all the blocks.

7.7.3.5.2.3.1 CAC Back Mapping

Offset table defines a (□x, □y) vector for a regular grid of output points. Each grid will define 2 offset vectors one each for EVEN and ODD line(s), defining how far output pixel needs to be moved in either direction. Final pixel location in input source image is used to compute the output pixel. Offset table can have precise definition and can capture rapidly changing offset tables. However it will require a large amount of memory. Since most offset tables are not expected to change rapidly in a small spatial region, CAC uses a subsampled offset table. Grid is down sampled with down-sampling factor in the range of 8 to 128 with increments of 4 in both horizontal and vertical directions. Subsampling factor is set in the register; BLOCKSZ.SIZE This enables reducing the amount of memory required to describe the offset vectors, but requires hardware to interpolate the missing offset vectors. CAC supports bilinear interpolation to interpolate missing offset vectors.

The mapping procedure is described by the following series of equations. Given an output pixel at location (x_0,y_0), we compute the input image pixel location (x_1,y_1).

Copyright © 2026 Texas Instruments Incorporated

$$ind_x = \frac{X_o}{Blk_{size}};\ f_x = MOD\left(X_o, Blk_{size}\right) \quad (11)$$

$$ind_y = \frac{Y_o}{Blk_{size}};\ f_y = MOD\left(Y_o, Blk_{size}\right) \quad (12)$$

Clip new index to Offset grid boundaries.

$$i_x = CLIP(ind_x, Grid_{HCnt}) \quad (13)$$

$$i_y = CLIP\left(ind_y, Grid_{VCnt}\right) \quad (14)$$

$$\Delta x_p = \frac{\left(\left(blk_{size} - f_y\right) \cdot T_{x0} + f_y \cdot T_{x1} + \frac{square(blk_{size})}{2}\right)}{square(block_{size})} \quad (15)$$

$$\Delta y_p = \frac{\left(\left(blk_{size} - f_y\right) \cdot T_{y0} + f_y \cdot T_{y1} + \frac{square(blk_{size})}{2}\right)}{square(block_{size})} \quad (16)$$

Clip to Horizontally to -8.0 to +8.0 pixel range (-64 to +64 with Q3 precision).

Clip to Vertically to -4.0 to +4.0 pixel range (-32 to +32 with Q3 precision).

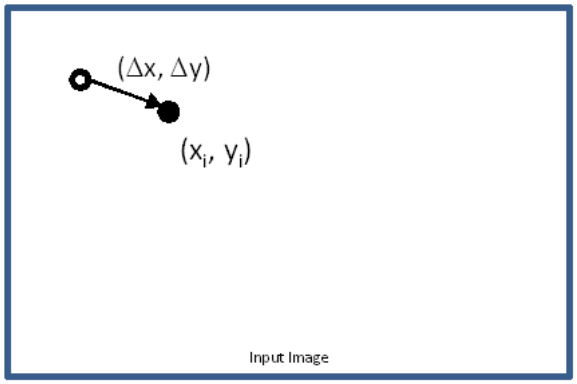

Figure 7-55. Back Mapping Procedure Using Offset Table

The input coordinate (x1,y1) refers to final input frame co-ordinates.

7.7.3.5.2.3.1.1 Offset Table Storage Format

The size of the offset table is dependent on the output frame size. The size must be:

$$\text{Table Width} = CEIL\left(\frac{\text{Frame Width}}{Blk_{size}}\right) + 1 \quad (17)$$

$$\text{Table Height} = CEIL\left(\frac{\text{Frame Height}}{Blk_{size}}\right) + 1 \quad (18)$$

The Offset table should be stored with □x and □y offsets interleaved and stored in raster order. Each offset is S8Q3, so a table entry is 32-bits, including both □x and □y for both Even and Odd line. Each line captures offset for one color either Red or Green.

7.7.3.5.2.3.2 Pixel Interpolation

Copyright © 2026 Texas Instruments Incorporated

As the coordinates calculated by the back mapping function are not integer values in most cases, b-cubic interpolation is applied to the back mapped pixels. Interpolation is done on the pixel of same color (either Red or Blue).

Output pixel is interpolated from the 16 pixels in the 4x4 grid around the back mapped location, as shown in Figure 7-56. *Ri* and *Bi* indicate integer co-ordinates of back mapped pixels. Bi-cubic interpolation is used first along the horizontal direction, then the vertical direction.

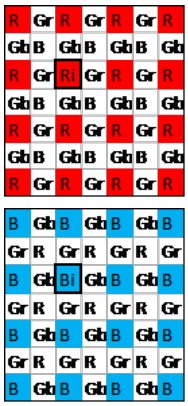

Figure 7-56. Bi-Cubic Interpolation Input Data

7.7.3.5.2.3.3 Bi-cubic Coefficients

The following coefficients are used for bi-cubic operation. Though back-mapped pixel has Q3 precision, there are 16 fractional phases due to Bayer pattern. The filter coefficients should be in S12Q10 format (signed 12-bit with 10 bits of fraction).

Phase	Coefficients (S12Q10)			
0/16	0	1024	0	0
1/16	-28	1014	40	-2
2/16	-49	987	93	-7

7.7.3.6 VISS Spatial Noise Filter (NSF4V)

7.7.3.6.1 NSF4V Introduction

7.7.3.6.1.1 NSF4V Features

For a list of features supported by the NSF4V module, see Section *VPAC Features*.

Some additional NSF4V parameters include:

- Input image format: any 2x2 raw color pattern
- Frame Width: limited to 4096
- Throughput:
  - 1 pixel in/out per clock
- Back Pressure Mechanism:
  - Input clock gating
  - Vert line sync
    - 7 extra lines of clocks plus enough clocks to flush pipeline

7.7.3.6.1.2 NSF4V Not Supported Features

NSF4V does not support the following features:

- Edge Enhancement
- YUV formats
- Module bypass (it is impemented at top subsystem level)

7.7.3.6.2 NSF4V Overview

The advanced noise filter NSF4v decomposes the input image into low-frequency, mid-frequency, and high-frequency bands first and then filter out the noise in frequency domain. NSF4v can adapt its noise filtering strength to local image intensity according to the user programmable noise threshold registers. NSF4 is also able to adjust its strength according to the amount of previously applied lens shading correction gains with a user programmable approximate radial model.

7.7.3.6.2.1 Decomposition Kernel Representation

With combination of just level 1, levels 1+2, and levels 1+2+3, horizontally and vertically, the result feature detection filter kernels are shown in Figure 7-58. Note that all coefficients are powers of 2, and therefore do not require multiplication.

Copyright © 2026 Texas Instruments Incorporated

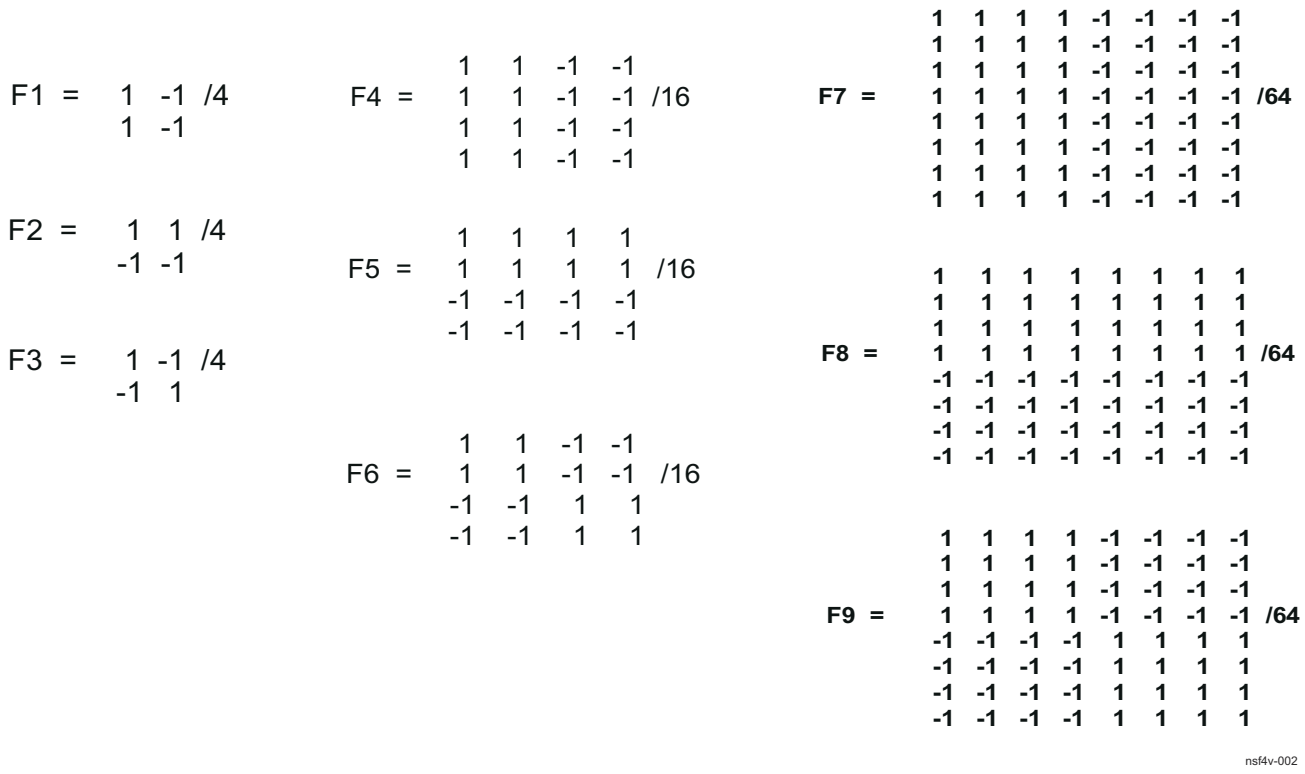

Figure 7-58. NSF4V Kernel Representation for Decomposition Filters

G1...9 are the counter-part reconstruction kernels. Each of G1...9 is a row-wise and column-wise mirror of the counterpart F function.

The kernel representation in Figure 7-59 illustrates a filter alignment.

Copyright © 2026 Texas Instruments Incorporated

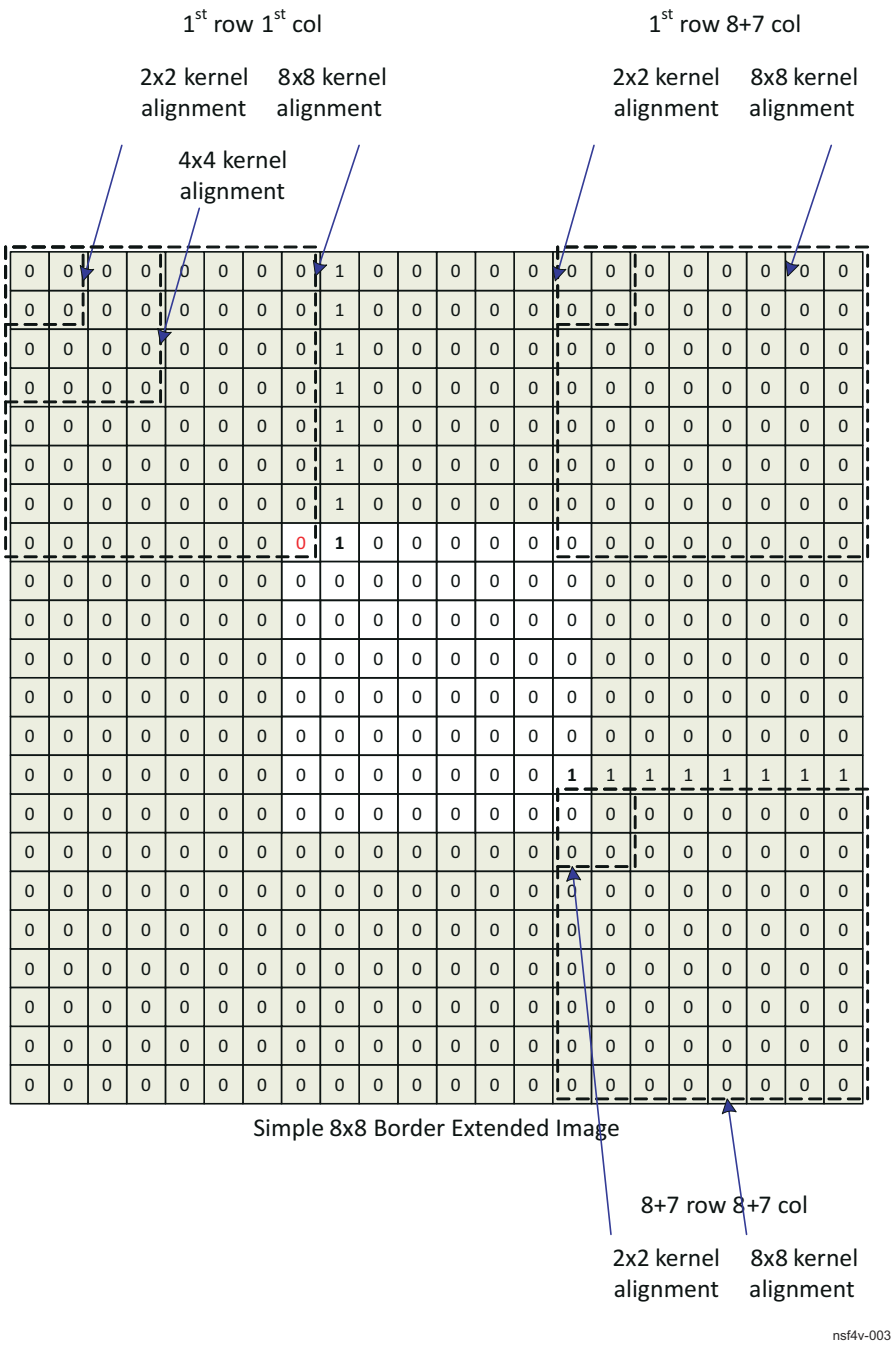

Figure 7-59. NSF4V Kernel Representation Filter Alignment

Figure 7-59 is showing an academic 8x8 pixel image frame which has been border extended on all 4 edges. Superposed onto this border extended frame (shown in dotted lines) is the kernel alignment for all 3 different kernel sizes for each of the three levels:

- Level 1: 2x2 kernel
- Level 2: 4x4 kernel
- Level 3: 8x8 kernel

For each of the 9 different kernels, a matrix of (width + 7) x (height +7) decomposition values result. All of these result matrixes are exactly aligned.

nsf4v-004

Figure 7-60. NSF4V Example F1 Kernel Result

The kernel alignment is top-left aligned for the first pixel. Which translates in the recursive approach as a X-Y shift. In order to be mathematically aligned in the Recursive approach, the Level 1 output needs to be shifted 6 positions in both the X and Y direction relative to the Level 3 output. Additionally, the Level 2 output needs to be shifted 4 positions in both the X and Y direction relative to the Level 3 output. These shifts are critical such that Level 1, 2, and 3 values are cycle aligned when presented to the thresholding circuit.

One can reach the same conclusion by looking at the figure and thinking about which line delay or which horizontal pipelined pixel position is used in order for the kernels to output their results in the same pipeline cycle.

7.7.3.6.3 NSF4V Lens Shading Correction Compensation

The Lens Shading Correction (LSC) is implemented prior to NSF. This is not an optimal order of operation and therefore an adjustment factor is implemented to compensate for the order of operations. The LSCC (Lens Shading Correction Compensation) first approximates the gain of LSC and calculates both that gain and it's inverse. Within the T_n calculation, the inverse gain is applied to the LL2 average, then the T_n is calculated. Last, the result is multiplied by the gain. In this way, the LSC is approximately reversed temporarily in order that T_n is calculated properly.

LSCC calculates the radius (distance) from the center of the image, then uses a programmable curve to look up the gain value.

While calculating the radius, the center on the frame is programmable. Also a correction gain (kh and kv) separately for X and Y are programmable which allows for elliptical shaped lenses. Because the SQRT is such an expensive function, the resulting radius is used in the SQR form and as such has a very large dynamic range. A programmable shift value effectively selects which portion of this dynamic range is to use for the curve lookup.

The curve lookup is a 16 segment curve. The SQR(Radius) is lookup on the X axis and the resulting gain is supplied on the Y axis.

Copyright © 2026 Texas Instruments Incorporated

7.7.3.6.4 NSF4V Noise Threshold Adaptation to Local Image Intensity

Figure 7-61 shows the local image intensity to noise threshold T_n mapping via the 12-segment interpolated lookup. Twelve sets of (X, Y, S), S = slope, are provided per curve, one set per color plane, with the first X coordinate fixed at zero.

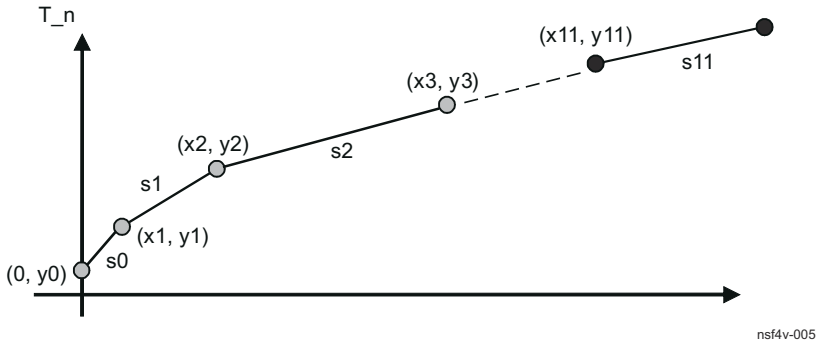

Figure 7-61. NSF4V Local Image Intensity to Noise Threshold Piece-wise Linear Function

The slopes should be implemented with signed value, as some image sensors might require higher noise threshold at the low intensity range than high intensity range.

7.7.3.7 VISS Global/Local Brightness and Contrast Enhancement (GLBCE) Module

7.7.3.7.1 GLBCE Overview

The Global Local Brightness Contrast Enhancement module performs dynamic range compression or tone mapping of an input image based on a model of the human visual system. It is used to produce most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations.

7.7.3.7.2 GLBCE Interface

Data flow control of GLBCE module is done by PCLK. GLBCE processes the image cycle by cycle, and output the data after certain cycles of latency.

7.7.3.7.3 GLBCE Core

The GLBCE Core is an iridix® core which performs "dynamic range compression" or "tone mapping" on an input image based on a model of the human visual system. It is used in a camera pipeline to produce the most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations. The purpose of the transform is to map the image content from an input source such that it remains fully visible on an output display without loss of content. Note that iridix is specifically designed to preserve color, sharpness and boost contrast of the source image.

The iridix core is based on space-variant or pixel-by-pixel processing algorithms which construct a family of transforms based on the analysis of image content. The algorithms inside iridix are adaptive, meaning that a single set of parameters can be set to process any source image or any video sequence under different lighting conditions.

Iridix generates effective tone curves by analyzing the regions surrounding each pixel. The tone curves generated by iridix are based on an asymmetry curve which is then shaped and controlled by a number of parameters that control the gain limitation weighting towards shadows, mid tones and highlights.

7.7.3.7.3.1 GLBCE Core Key Parameters

Table 7-106 shows the key parameters within the iridix core. It is recommended that all parameters be set statically to their recommended values other than the iridix strength parameter, which should be controlled dynamically with scene content. The calculation of iridix strength is explained in Section 7.7.3.7.3.2.

Table 7-106. GLBCE Core Key Parameters

Parameter	Description
iridix strength	This register sets iridix processing strength.
	0x00: Video data will not be processed at all, and will pass to the output unchanged.
	0xFF: Maximum processing strength.
Variance space	This register affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). If this parameter is set to zero, the sensitivity to small areas is maximized (i.e. the transform becomes more local). When this parameter is set to 0xF, the transform deemphasizes small local details, and the transform becomes more global
Variance intensity	For a high-contrast image with shadows and highlights, a small value will cause iridix to adjust shadows and highlights almost independently. A large variance causes iridix to become progressively more global, meaning that the presence of highlights affects the processing of shadows and vice-versa.
Slope min limit	This register is used to restrict the slope of the tone curve generated by iridix. When this parameter is set to 0x00, the tone curve slope generated by iridix is not limited.
	When this value is set to 0xFF, iridix will not generate a tone curve with a slope less than 3/4. Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-128
Slope max limit	This register is used to restrict the slope of the tone-curve generated by iridix. When this parameter is set to 0xFF, the tone curve slope generated by iridix is not limited.
	When this value is set to 0x00, iridix will not generate a tone-curve with slope greater than 16/15 (48°). Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-160. For noisy images, lower values should be used.

Copyright © 2026 Texas Instruments Incorporated

Table 7-106. GLBCE Core Key Parameters (continued)

Parameter	Description
Black level	The value stored in this register will be used as the zero level for iridix processing in all data channels. Data below this value will not be processed and remain unchanged.
White level	The value stored in this register will be used as the white level for iridix processing in all data channels. Data above this value will not be processed and remain unchanged.
Asymmetry LUT	This look-up-table is 33 words, each of which is 16-bits. The asymmetry function is used to balance the iridix effect between the dark and bright regions of the image.
Forward perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is presented to the core, this look-up-table must be used to map the linear data to the perceptual space so that iridix can perform tis perceptual functions.
Reverse perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is required from the output of the core, this look-up-table must be used to map the data from the perceptual space back to linear space for further processing in the pipeline.

7.7.3.7.3.2 GLBCE Iridix Strength Calculation

This section describes how the dynamic parameter, iridix strength, is calculated.

Note

Dynamic range of a digital camera can be described as the ratio of maximum light intensity measurable (at pixel saturation), to minimum light intensity measurable (but above read-out noise). This is a very important concept to consider when computing iridix strength, because the gain applied by iridix is also proportional to the visible boost of noise in the image. The maximum gain applied by iridix should be determined by the dynamic range of the camera system. This is governed by the equation presented in this section.

With iridix strength is zero, all tone curves are linear for all images. As iridix strength is increased, the variation between curves in shadows, mid tones and highlights increases, resulting in increasing compression of global dynamic range.

Iridix strength is calculated as follows:

$$\text{iridix strength} = \text{Max}\left(0, \text{Min}\left(\frac{\text{IR_Gain_Target} - 1}{\text{IR_Gain}_{\text{Max}} - 1}, \text{f}\left(\text{analog gain}\right)\right)\right) \times 255 \quad (19)$$

Where:

- IR_Gain_Target is the desired iridix gain to be applied to the image. This is calculated from the image's histogram on a per-frame basis by the auto exposure algorithm (in RAWFE H3A module). The histogram is analysed to compute an exposure ratio for the desired global histogram shift. This computed exposure ratio is then used to feed a look-up-table which in turn generates the IR_Gain_Target parameter.
- IR_GainMax is the maximum iridix gain. If the fwd_percep_lut is disabled, then the IR_GainMax should be set to 64, and if the fwd_percep_lut is enabled, then the IR_Gainmax should be set to 16.
- f(analog gain) is a function that determines the maximum iridix strength in relation to noise. f(analog gain) is characterised as follows:

Copyright © 2026 Texas Instruments Incorporated

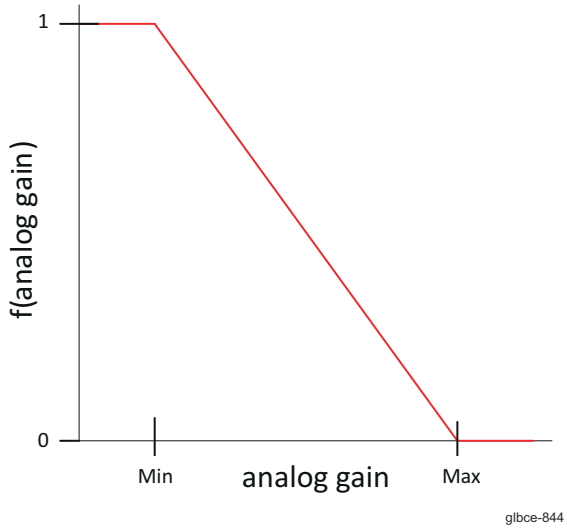

Figure 7-62. GLBCE Iridix f(Analog Gain) Function

f(analog gain) should only be used when the RAWFE is in linear mode. Otherwise, it should be set to 1

7.7.3.7.3.3 GLBCE Iridix Configuration Registers

7.7.3.7.3.3.1 GLBCE Iridix Frame Width

Frame Width is the number of pixels in an active line and is controlled from GLBCE_FRAME_WIDTH[15:0] VAL. Recommended value 2560 (decimal)

7.7.3.7.3.3.2 GLBCE Iridix Frame Height

Frame Height is the number of active lines in a frame and is controlled from GLBCE_FRAME_HEIGHT[15:0] VAL. Recommended value 1920 (decimal)

7.7.3.7.3.3.3 GLBCE Iridix Control 0

This is the main control register for the iridix core is GLBCE_CONTROL0 where GLBCE is enabled/disabled and the type of processing algorithm is selected.

7.7.3.7.3.3.4 GLBCE Iridix Control 1

This register is reserved for debugging purposes. Recommended value 6 (decimal)

7.7.3.7.3.3.5 GLBCE Iridix Strength

GLBCE_STRENGTH_IR[7:0] VAL register sets the processing strength of the iridix core. Recommended value 128 (decimal)

7.7.3.7.3.3.6 GLBCE Iridix Variance

The GLBCE_VARIANCE parameter affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). GLBCE_VARIANCE[7:4] VARIANCEINTENSITY recommended value 12 (decimal). GLBCE_VARIANCE[3:0] VARIANCESPACE recommended value 7 (decimal).

7.7.3.7.3.3.7 GLBCE Iridix Dither

When the number of color gradations of a display device is small (for example 6 bits per color), pixel dithering can make gradients look smother. Dithering of the least significant bits is applied and then these bits can be later truncated. The three least significant bits (D2, D1, D0) of this GLBCE_DITHER register are responsible for the strength of dithering. There are 4 possible levels of dithering. Recommended value 0 (decimal)

Copyright © 2026 Texas Instruments Incorporated

7.7.3.7.3.3.8 GLBCE Iridix Amplification Limit

The parameters dark amplification limit and bright amplification limit are used to restrict the luminance space in which iridix can adaptively generate tone curves for each pixel. GLBCE_LIMIT_AMPL[7:4] BRIGHTAMPLIFICATIONLIMIT recommended value 0 (decimal). GLBCE_LIMIT_AMPL[3:0] DARKAMPLIFICATIONLIMIT recommended value 0 (decimal).

7.7.3.7.3.3.9 GLBCE Iridix Slope Min and Max

GLBCE_SLOPE_MIN[7:0] SLOPEMINLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 64 (decimal).

GLBCE_SLOPE_MAX[7:0] SLOPEMAXLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 72 (decimal).

7.7.3.7.3.3.10 GLBCE Iridix Black Level

The value stored in the Black Level register GLBCE_BLACK_LEVEL[15:0] VAL will be used as the zero level for iridix processing in all data channels. Data below the Black level will not be processed and remain unchanged. Recommended value 0 (decimal).

7.7.3.7.3.3.11 GLBCE Iridix White Level

The value stored in White Level register GLBCE_WHITE_LEVEL[15:0] VAL will be used as white level for iridix processing in all data channels. Data above White level will not be processed and stay unchanged. Recommended value 65535 (decimal).

7.7.3.7.3.3.12 GLBCE Iridix Asymmetry Function Look-up-table

The Asymmetry function is used to balance the iridix effect between the dark and bright regions of the image. The Asymmetry Function Lookup Table geometry is 33 words, each of which is 16-bits wide.

                AsymmetryTable[ii] = y;
            }
        }
```

7.7.3.7.3.3.13 GLBCE Iridix Forward and Reverse Perceptual Functions Look-up-tables

The iridix core works in a perceptually uniform space and thus when linear data is presented to the core it needs to be processed with special perceptual functions. These are implemented as two perceptual LUTs namely: Forward Perceptual LUT and Reverse Perceptual LUT. Each LUT is made up of sixty-five 32-bit words.

7.7.3.7.4 GLBCE Embedded Memory

GLBCE needs 2 lines of line memories and 1 set of cache memories.

Table 7-107. GLBCE Memories

Memory Type	Qty	Size	Clock	ECC Supported	Description
DELAY LINE	1	2122 x 64 (GLBCE_LINE_SIZE /2+10)x64	FCLK	No	GLBCE line memory
STATMEM	8 banks	16 bit x 1024	FCLK	Yes	GLBCE Cache memory (computes and stores the statistics from the frame)

7.7.3.7.5 GLBCE General Processing

GLBCE block needs appropriate statistics information to be stored to its cache memory in prior to processing incoming frame. Usually, this takes a two-pass process.

1. GLBCE is configured for input frame-A
2. Frame-A is given to GLBCE
3. GLBCE processes the input frame-A
4. GLBCE generates statistic (statistics-A) data based on frame-A in vertical blanking period
5. (Optional process) statistics-A is read from cache memory and moved to SDRAM
6. GLBCE is configured for input frame-B
7. Frame-B is given to GLBCE
8. GLBCE processes the input frame-B with the statistics-A generated from frame-A
9. GLBCE generates statistics-B based on frame-B in vertical blanking period
10. (Optional process) statistics-B is read from cache memory and moved to SDRAM

Alternatively, GLBCE can process in the following manner

1. Pre-calculated Statistics-C is copied to GLBCE cache memory from SDRAM
2. GLBCE is programmed for input frame-D
3. Frame-D is given to GLBCE
4. GLBCE processes frame-D based on statistics-C
5. GLBCE generates statistics-D based on frame-D in vertical blanking period
6. (Optional process) statistics-D is read from cache memory and moved to SDRAM

In Section 7.7.3.7.6, some examples closer to real world use cases are explained based on the above two processes.

7.7.3.7.6 GLBCE Continuous Frame Processing

This is a very basic case, which does not need transferring statistics between cache memory and SDRAM. The most common example is video capture. In this case, the most straight forward way to run GLBCE, is to generate statistics from N-th frame, and apply it to (N+1)-th frame. The effect from using statistics of different frame should be small if the difference between frames is small. For example, it is expected this does not generate artifact, if the video frame rate is 30fps or larger. Below this rate, the single frame processing programming model explained in Section 7.7.3.7.7 should be considered.

In the case of continuous frame processing, GLBCE is operated in the following manner:

Copyright © 2026 Texas Instruments Incorporated

1. GLBCE is programmed for incoming frame
2. Input frame comes in
3. GLBCE processes Input frame based on the statistics from the previous frame
4. GLBCE generates statistics based on the current input frame in the vertical blanking period
5. Repeat Step 1 through 4 as required

For the first frame of a set of sequential frames, Strength parameter should be 0, so GLBCE does not affect the image based on wrong statistics. SW may need to increase the strength value gradually after the first frame.

7.7.3.7.7 GLBCE Single Image Processing

For a single image, GLBCE needs to process the image twice, once for statistics generation, and once for actual GLBCE process.

1. GLBCE is configured for the input image.
2. The image is given to GLBCE. (Output image from GLBCE should be surpressed, for example, by disabling the next module in the path)
3. Statistics is generated in vertical blanking period.
4. The input image is given to GLBCE again. Output image with right GLBCE is generated.

   Also, GLBCE can take in small size image in the first pass to reduce processing time.
5. A small size version (IMG-S) of the input image (IMG-IN) is generated.
6. GLBCE is configured for the small size image (IMG-S).
7. The small size image (IMG-S) is given to GLBCE.
8. Statistics for the small size image is generated in vertical blanking period.
9. GLBCE is configured for the original input image (IMG-IN).
10. The original input image (IMG-IN) is given to GLBCE.

7.7.3.8 VISS Flexible Color Processing (FCP) Module

7.7.3.8.1 FCP Overview

The Flexible Color Processing module is responsible for performing CFA Interpolation as well as performing a host of color processing functions for generating different color outputs.

7.7.3.8.1.1 FCP Features Supported

The FCP include the following main features:

- Flexible CFA for generating multi-plane output for any 2x2 raw format sensor configuration.
  - Supports RCBC, RCCC, Bayer, RGBC as well as other formats
  - Can generate up to 4 independent color planes
  - Support for up to 3 directions per color plane
  - Adaptive Threshold based on intensity measure
- Support for multiple color format output generation:
  - Support 12-bit YUV output
  - Supports RGB output
  - Supports Saturation outputs (8 bits only)
  - Supports Grayscale/Luma/IR/Clear output.
- Support for 16 to 12 compression (LUT based) at the entry of the block
- Support for flexible output format generation including YUV as well as RGB, SV, and so forth.
- Single cycle/pixel performance

7.7.3.8.2 FCP Functional Description

The Flexible Color Processor (FCP) receives data from RAW-FE and does demosaicing and color conversion. The output of FCP is sent to external memory.

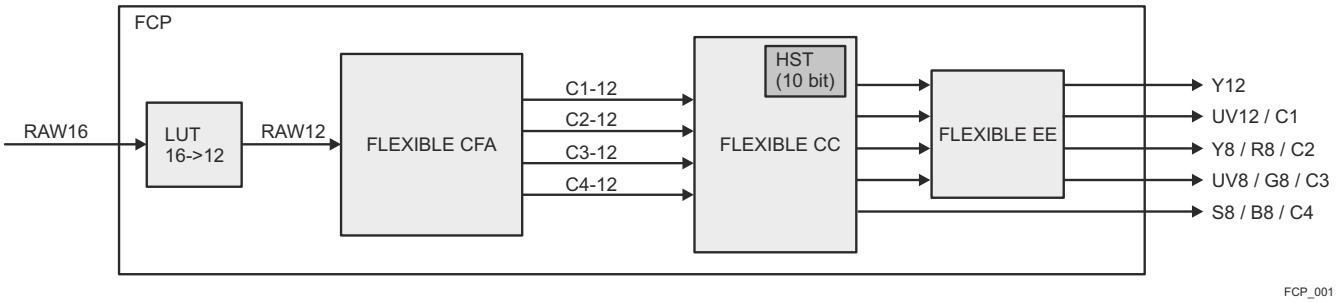

Figure 7-63. FCP Block Diagram

The FCP consists of the following major sub-blocks for supporting different sensor and output formats:

- LUT based compression: used to reduce the bit width from 16 bits to 12 bits while still preserving the dynamic range.
- Flexible CFA: this block takes in as input any 2x2 raw sensor pattern and is capable of generating up to 4 full resolution color planes.
- Flexible Color Conversion (Flexible CC): this block takes in the output of the Flexible CFA and generates multiple standard as well as custom data formats.
- Flexible Edge Enhancer (Flexible EE): this block can take the output of the Color Conversion and align the Y and UV channels as well as enhance the edges in the luma channel.

7.7.3.8.3 FCP Submodule Details

7.7.3.8.3.1 Flexible CFA / Demosaicing

7.7.3.8.3.1.1 Feature-set

The Flexible CFA include the following main features:

- Support for Flexible CFA for generating multi-plane output for any 2x2 raw format sensor configuration.
  - Supports RCBC, RCCC, Bayer, RGBC as well as other formats.

Copyright © 2026 Texas Instruments Incorporated

  - Can generate up to 4 independent color planes.
  - Supports Clear (C) pixel.
  - Supports Infrared (IR) pixels.
- Edge aware CFA interpolation.
- Software programmable filter for interpolation up to 4 color channels.
- Support for up to 4 phases and 3 directions per color channel.
- Software controlled algorithm for direction selection.
- Adaptive threshold calculation for direction selection.
- Support of up to 2 sets of programmable mask based gradient selection

7.7.3.8.3.1.2 Block Diagram of Flexible CFA

The Flexible CFA module follows the VPORT (internal) interface for both the input/output to the RAW-FE or Flexible CC module.

7.7.3.8.3.1.2.1 Gradient/Threshold Calculation

The Flexible CFA incorporates 2 sets of gradient and direction selection logic. Typically for symmetric 2x2 patterns like Bayer, only a single set is sufficient; however in sensors wherein one of the channels is working on a different data type, the second set can be used for that channel. An example of such sensors is the RGB-IR sensor, wherein the 2x2 pattern consists of one pixel of each color channel and one pixel of the IR channel. In this case, mixing the gradients and intensity of the color channels with the IR channel could be meaningless.

The gradient selection uses bit masks to select the desired pixel position for calculating the horizontal and the vertical gradient.

Figure 7-64 shows the notation for the bit-mask values. The same notation is used for vertical masks as well and the notation implies that setting a ‘1’ in any field of the bit Mask enables the absolute difference of those 2 pixels to be summed in the gradient calculation.

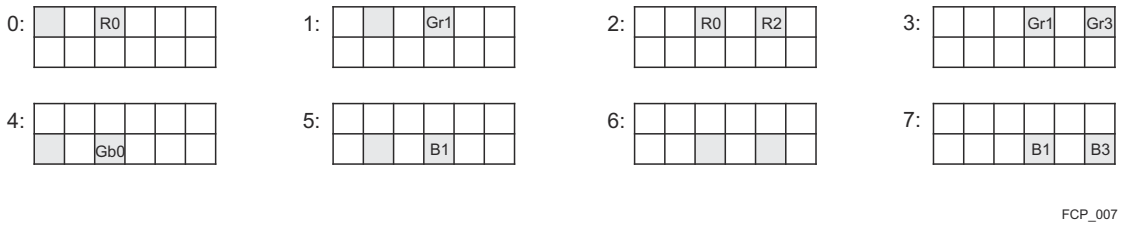

Figure 7-64. Gradient Bit Masks

Similar masks are also used to calculate the intensity (see Figure 7-65), however instead of taking the absolute difference, the bit masks are used to sum up the pixels in those locations.

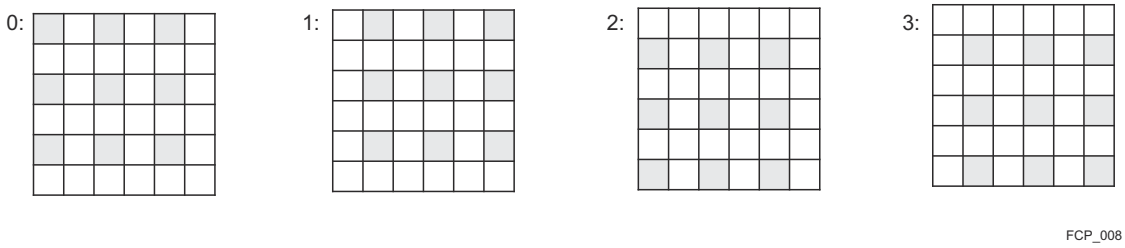

Figure 7-65. Intensity Bit Mask

The 4 bit Intensity mask is used to choose which pixels in the 6 rows should be used for creating the intensity sum. The same masks are used for every 2x2 window within the 6x6 buffer. (Thus setting all 4 bits to ‘1’ will be equivalent to summing up the entire 6x6 window.) A programmable shift is then used to bring the intensity down to the 0-16k range. The maximum value of intensity can be 6x6 x4k = 144k, so the maximum value of shift is 4 (divide by 16). The shift value can be programmed to any value between 0 and 4 and should be chosen based

Copyright © 2026 Texas Instruments Incorporated

on the mask. Note that dependent on the shift value, it's possible that the full range of 0-16k of the intensity may not be reached, hence the adaptive threshold should be programmed accordingly.

The adaptive threshold calculation uses the calculated intensity. For more information, see Section 7.7.3.8.3.1.2.2, *Software Controlled Direction Selection*.

7.7.3.8.3.1.2.2 Software Controlled Direction Selection

Software can control or guide direction selection at frame or sequence level as shown in Figure 7-66.

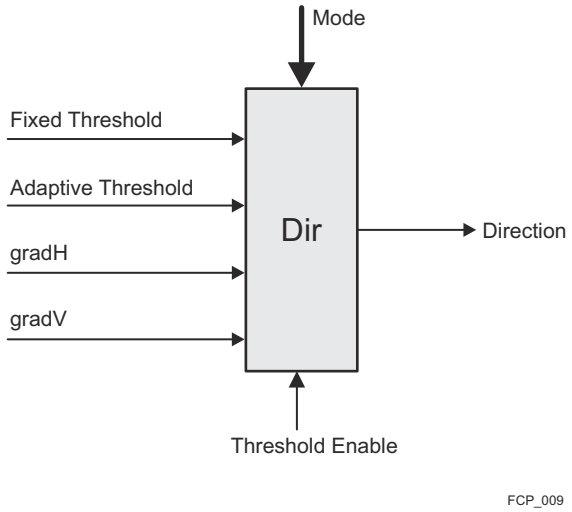

Figure 7-66. Software Controlled Direction Selection

Table 7-108 summarizes number of option available to software.

Table 7-108. Summary of HSX Spaces

Mode	Name	Details
0	Horizontal	Dir = 0
1	Vertical	Dir = 1
2	HV	Dir = 2
3	HV_Threshold (Fixed threshold is MMR)	in Dir = 0: gradH ≥ gradV + threshold in Dir = 1: gradV ≥ gradH + threshold in Dir = 2: Otherwise
4	HV_AdaptiveThreshold	in Dir = 0: gradH ≥ gradV + threshold in Dir = 1: gradV ≥ gradH + threshold in Dir = 2: Otherwise

For calculation of adaptive threshold, 7 options are used. Each one defines a threshold to be used as a different intensity level as it follows:

- Entry-0 -> Intensity = 0
- Entry-1 -> Intensity = 512
- Entry-2 -> Intensity = 1024
- Entry-3 -> Intensity = 2048
- Entry 4 -> Intenisty = 4096
- Entry 5 -> Intensity = 8192
- Entry 6 -> Intensity = 16384

The adaptive threshold can then be calculated as a linear interpolation between 2 successive entries based on the given intensity.

Copyright © 2026 Texas Instruments Incorporated

7.7.3.8.3.2 Edge Enhancer Module Wrapper (WEE)

Figure 7-67 shows a high level block diagram of the Edge Enhancer (EE) module wrapper. For more information about the Edge Enhancer algorithm, see *Edge Enhancer (EE)*. The wrapper places the Edge Enhancer within the FCP structure along with assotiated muxes.

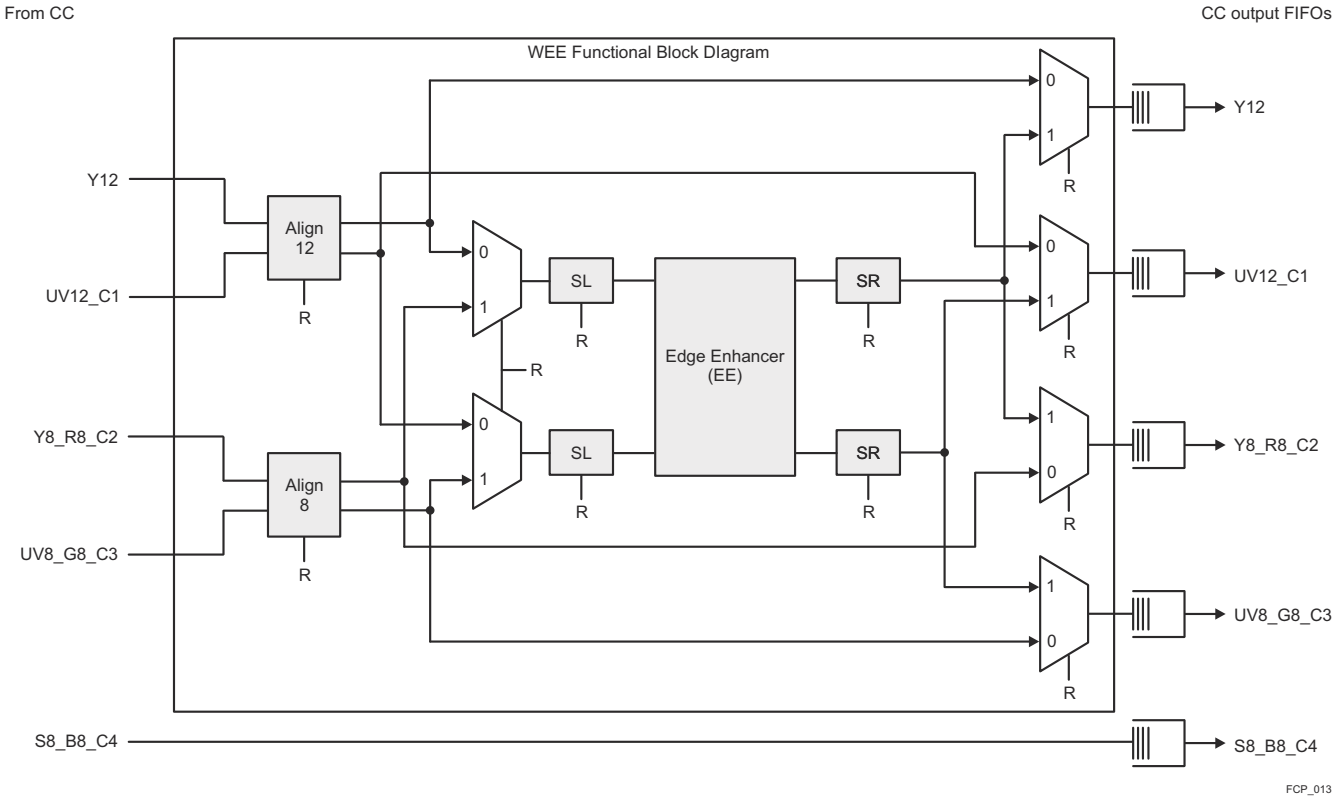

Figure 7-67. Block Diagram of Edge Enhancer Module Wrapper

7.7.3.8.3.2.1 EE - Edge Enhancer Block

The Edge Enhancer module is used to enhance the visual quality of the image by increasing its sharpness. The module only works on Y (Luma) data and uses a combination of 2D High-Pass Filtering to detect edges and then apply them on the input image.

7.7.3.8.3.3 Flexible Color Conversion (CC)

Figure 7-68 shows a high level block diagram of the Flexible Color Conversion (CC) module.

Copyright © 2026 Texas Instruments Incorporated

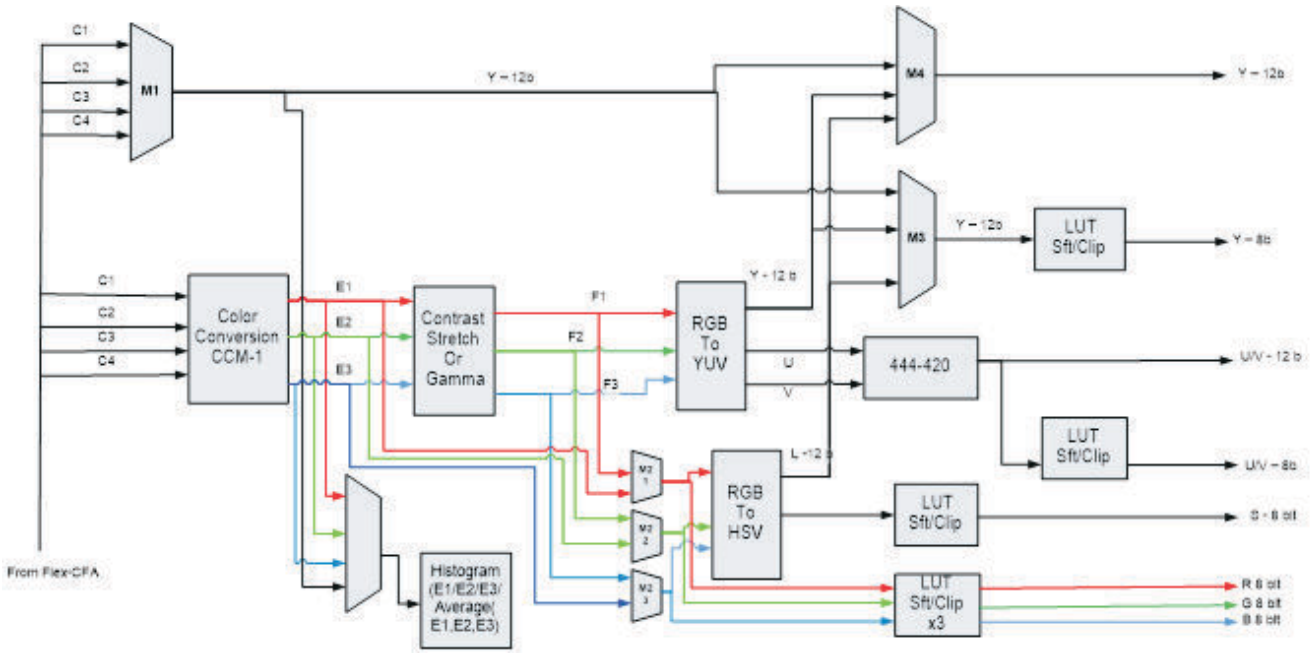

Figure 7-68. Flexible CC Block Diagram (Logical View)

The Flexible CC enables multiple use cases and allows different color formats to be generated.

The Flexible CC module follows the VPORT (Internal) Interface for both the input to the Flexible CC module.

7.7.3.8.3.3.1 Interface Mux

The Flexible CC logical block diagram has 5 primary outputs connecting to the LSE modules in the VISS. For more information about LSE modules, see *Load Store Engine (LSE)*. A multiplex scheme is used to connect multiple outputs on to 5 interfaces using the interface Mux. The Flexible CC output can optionally also allow data from Flexible CFA to be tapped out on to one of the primary interfaces. Note that 12-8 LUTs are shared between the RGB generation and the Y/UV 8-bit generation logic.

Figure 7-69 shows the details of the interface mux. There are only 3 LUTs shared in different mode and only 5 concurrent output streams can be activated at any point of time. For 8-bit outputs, the data is stored in the MSB 11-4 bits of the 12-bit bus. Further, the Y12 output is dedicated and not multiplexed with other interface signals.

Copyright © 2026 Texas Instruments Incorporated

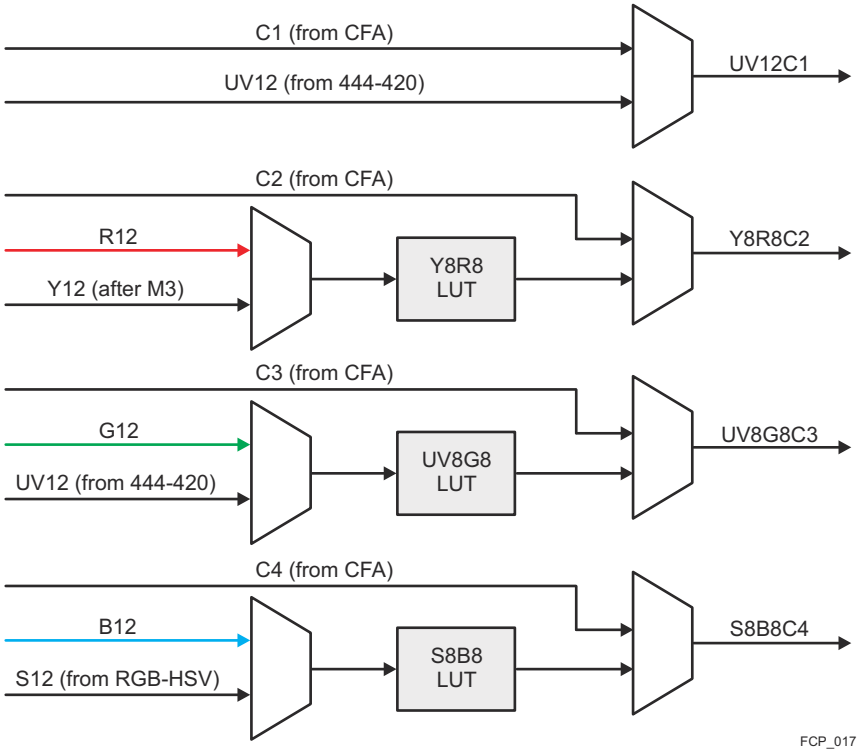

Figure 7-69. Flexible CC Interface Mux

7.7.3.8.3.3.2 Color Conversion (CCM-1)

The Color Conversion (CCM-1) is defined using the mathematical equations from Figure 7-70.

$$E1(x,y) = W11 \times C1(x,y) + W12 \times C2(x,y) + W13 \times C3(x,y) + W14 \times C4(x,y) + Offset_1$$
$$E2(x,y) = W21 \times C1(x,y) + W22 \times C2(x,y) + W23 \times C3(x,y) + W24 \times C4(x,y) + Offset_2$$
$$E3(x,y) = W31 \times C1(x,y) + W32 \times C2(x,y) + W33 \times C3(x,y) + W34 \times C4(x,y) + Offset_3$$

Figure 7-70. CCM-1

The CCM matrices weights (W**) are 12 bit signed each (S12Q8) representing a range from -8 to +7.996 with 8 bits of fraction. The offsets are 13 bit signed notation (S13Q11) representing a range of -4096 to +4095. The offset is effectively shifted by one (left shifted/ multiplied by 2) before being applied. The effective range of offset is -2 to +1.995 with 11 bits of fraction.

The 4 component CCM allows for a power combination of color format generation to be addressed.

7.7.3.8.3.3.3 RGB to HSX Conversion

The RGB-HSV module is used for converting color spaces and creating custom luminance data plane. This way the 8-bit Saturation and 12-bit Luminance (L or V) plane are generated.

Figure 7-71 shows the block which generates the Luminance / Gray Scale Plane as well as the Saturation (8-bit) plane.

Copyright © 2026 Texas Instruments Incorporated

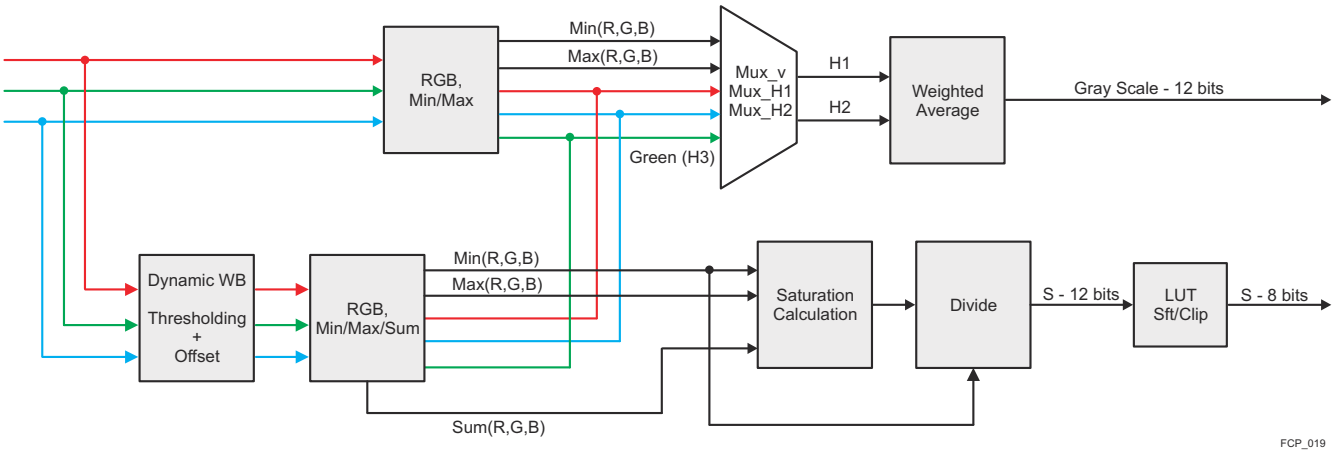

Figure 7-71. S & V Generation

7.7.3.8.3.3.3.1 Weighted Average Block

The Weighted Average block implements the equation shown on Figure 7-72.

$$GrayScale(x,y) = W1 \times H1(x,y) + W2 \times H2(x,y) + W3 \times H3(x,y) + Offset_1$$

Figure 7-72. Gray Scale Computation

In the equation on Figure 7-72 the Weights (W1*) are 12 bits signed with a range of -8 to +7.9996 in S12Q8 format. The offset is Signed 13 bits in S13Q11 format with a range of -2 to +1.995.

Figure 7-73 depicts the archtiectue of the Weighted Average block:

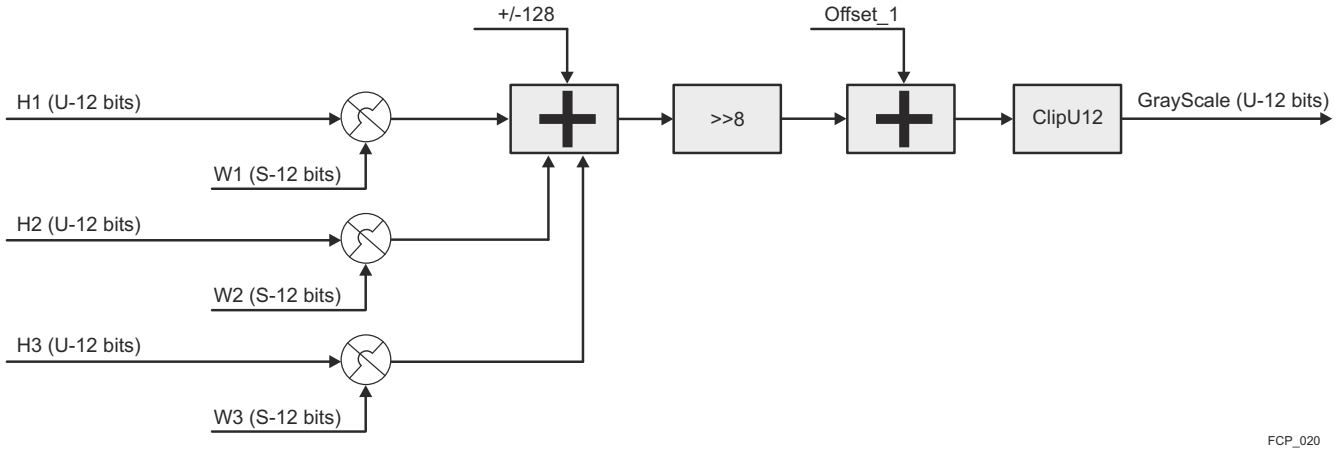

Figure 7-73. Weighted Average Block

The mux before the matrix chooses whether the native R/B channels are transmitted or alternatively the Min/Max (RGB) from the Min-Max block are transmitted. Further, the calculation of V can work on either the non-WB corrected data or the WB corrected version. For more information about WB correction, see Section 7.7.3.8.3.3.3.2, *Saturation Block*.

The combination of the Min-Max block, the mux and the Weighted Matrix allows any of the Gray Scale calculation as shown in Table 7-109.

Copyright © 2026 Texas Instruments Incorporated

Table 7-109. Summary of HSX Spaces

No	Formula	Configuration
Grey scale (HSI)	(R+G+B) / 3	H1 = R, H2 = B; Offset_1 = 0; W1 = W2 = W3 = 1/3 = 85;
Gray Scale (HSV)	Max(RGB)	H1 = Max(RGB); H2 = NA Offset_1 = 0; W2/W3 = 0; W1 = 1 (256);
Gey Scale HSL	(Max(RGB) + Min (RGB)) / 2	H1 = Max(RGB), H2 = Min(RGB); W1 = W2 = 0.5 (128) Offset_1 = 0; W3 = 0;
		H1 = R, H2 = G; W1 = W3 = 0.25 (64); W2 = 0.5 (128) Offset_1 =0

Table 7-110. Grey Scale and Saturation Calcuation

No	HSI Color Space	HSV Color Space	SHL Color Space	Customer Requirements
Grey Scale Computation	(R+G+B) / 3	Max(R,G,B)	(Max(R,G,B) + Min(R,G,B)) / 2	(R+2*G+B) / 3
Saturation (S) Computation	1-(Min(R,G,B) / (R+G+B))	(Max(R,G,B) - Min(R,G,B)) / Max(R,G,B)	(Max(R,G,B) - Min(R,G,B)) / 255-Gray value	S = Max(R,G,B) - Min(R,G,B)
Hue (H) Computation	Complex formula involving (R-G) (R-B) & (G-B)	Division formula livolving (R-G) (R-B) & (G-B)	Complex formula involving all component	Separate output for (R-G) and Yellowness

7.7.3.8.3.3.3.2 Saturation Block

The Saturation block first applies a dynamic white balance offset to correct the saturation plane when the image is in log domain and is used for analytics data flow. Once the WB offset is applied, the saturation calculation proceeds as described below. Note that the White balance offset is only applied if the independent pixel values are below a threshold (VISS_FCP_FCC_RGBHSV_WB_LINLOGTHR_1/2). Further, even the minimum of RGB is compared against a threshold (VISS_FCP_FCC_RGBHSV_WB_LINLOGTHR_2[27-16] SATMINTHR bit field) and the higher of the two is used. The saturation calculation always uses the data with the WB correction applied, however the V calculation can choose between WB corrected or uncorrected data using VISS_FCP_FCC_CFG_1[26] MUXRGBHSV_MUX_V.

Table 7-110 shows the condensed form for the Grey Scale and Saturation calculation. In the Flexible CC the saturation calculation is supported using two modes based on the VISS_FCP_FCC_CFG_2[6] HSVSATMODE bit as follows.

- HSVSATMODE = 0: Max(RGB) - Min(RGB)
- HSVSATMODE = 1: SUM(RGB) - Min(RGB)

Similarly the denominator for the dvision is chosen using the following selection on the VISS_FCP_FCC_CFG_2[5-4] HSVSATDIVMODE bit field.

- HSVSATDIVMODE = 0: No division, denominator = 1
- HSVSATDIVMODE = 1: Max(RGB)
- HSVSATDIVMODE = 2: 4095 – Gray value (computed in Figure 7-72)
- HSVSATDIVMODE = 3: Sum(RGB)

7.7.3.8.3.3.3.3 Division Block

The division operation is implemented to calculate 1/x followed by a multiplication with the value. The input to the LUT is 12-bit unsigned value and the output is 8-bits fraction representing 1/x calculation. The divide LUT is implemented as a non-linear ROM with 1216 (1280 for aligning to 128 size boundary) entries and up to 2 segments to reduce error. Ideally to implement a full ROM for an input space of 12 bits would require 4k entires, however to save space and reduce error, the ROM is partitioned such that it is full resolution for the first 256 entries where the curve is highly non linear, whereas the next 4k - 256 entires have a step size of 4. Each ROM entry has a bit size of 20 bits in U20Q20.

Copyright © 2026 Texas Instruments Incorporated

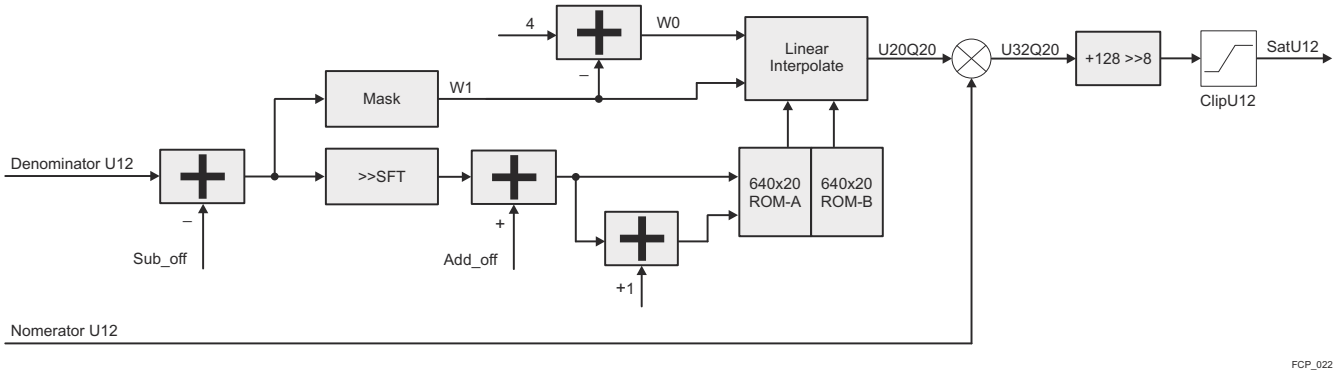

Figure 7-74. Division LUT

These are the parameters that need to be calculated based on the range of the input.

- SFT: '0' if input <256, 2 otherwise
- Mask: '0' if input <256, 4 otherwise
- Add_off: '0' if input <256, 256 otherwise
- Sub_off: '0' if input <256, 256 otherwise

The 'shift' parameter at the end is a configuration register which needs to be programmed. Typical programming value is 8 to generate a result in Q12 format (such that the range is 0 to1). This is usually the case when the denominator is greater than the numerator.

7.7.3.8.3.3.3.4 LUT Based 12 to 8 Downsampling

In the final step the generated saturation value (12 bit) or the incoming RGB values (12 bit) needs to be scaled down to 8 bits using the linear LUT with 513 entries.

Figure 7-75 is a high level block diagram of the LUT block. It shows the weight calculation for the LUT assuming the incoming data can be of any bit depth between 8 and 12 bits.

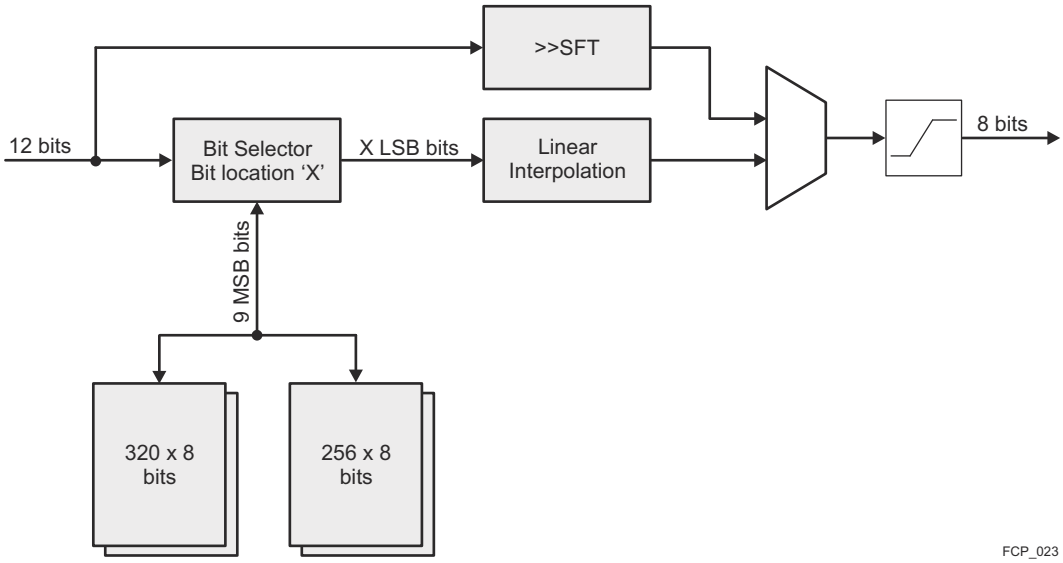

Figure 7-75. LUT Based 12-8 Compression

The LUTs are sized to provide 513 locations of data, to enable linear interpolation for all locations. The internal weights are sized as 3 bits since the maximum delta between 2 steps is only 4095/512 = 8.

Figure 7-76 shows the high level block diagram of the interpolation process. The logic is designed to scale for bit width and can support anything from 8 to 12 bits of input to support different usecases. However, since the

Copyright © 2026 Texas Instruments Incorporated

step size is different depending on the input bit width, the bit selection and weight calculation logic is designed to account for that.

A shift operation can be performed instead of LUT to reduce bitwidth from 12 down to 8 bits.

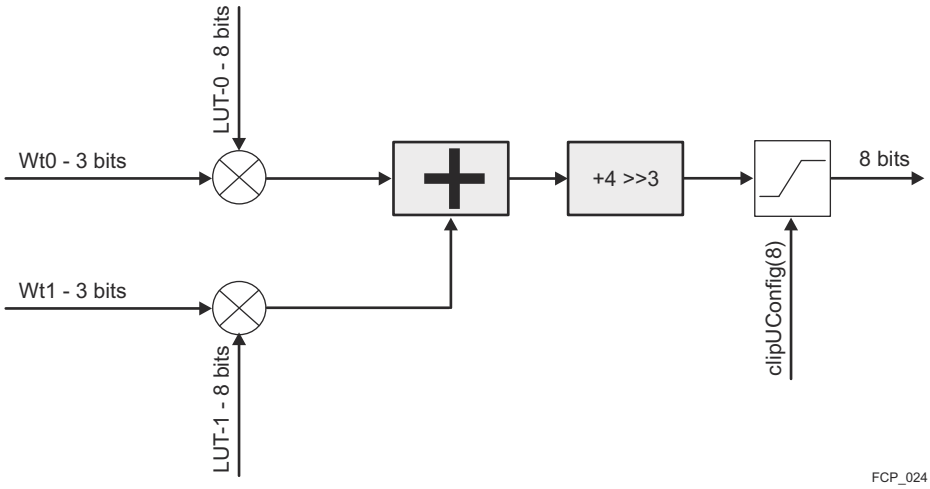

Figure 7-76. Linear Interpolation on LUT

The code below shows the addressing for the LUT as well as the weight calculation logic for supporting multiple bit widths at the input from 8 – 12 bits.

12-8 Bit LUT Curve

```
CASE BIT_SEL
12 (12 bit data): Addr = Inp[3:11]; Wt1 = Inp[2:0]
11 (11 bit data): Addr = Inp[2:10]; Wt1 = Inp[1:0] & '0'
10 (10 bit data): Addr = Inp[1:9]; Wt1 = Inp[0] & '00'
9 (9 bit data): Addr = Inp[0:8]; Wt1 = '000'
8 (8 bit data): Addr = Inp[0:7]; Wt1 = '000';
//Wt0 is always calculated at 8 - Wt1
Wt0 = 8 - Wt1
```

The input bit width (BIT_SEL) is specified using a dedicated register for generating Y8 output. However for other paths (RGB/UV/Sat) the 8 bit conversion is done using either 12 bits (if data is tapped prior to contrast block) as the bitwidth or the clipping value after contrast block (VISS_FCP_FCC_CFG_2[12-9] CONTRASTBITCLIP, if data is tapped after contrast block).

7.7.3.8.3.3.4 Histogram

The histogram can work on either one of the color components after the CCM-1 or the fourth color component routed directly from the Flexible CFA. The Histogram can also work on internally generated Luma value using simple averaging of RGB components. The Histogram module supports a local memory which can be read by the host processor. The Histogram provides data which can be used by the software to generate tone curves for the Contrast Stretch LUT.

The input to the Histogram module is calculated based on the control MMR as it follows:

- 0: R
- 1: G
- 2: B
- 3: MuxC1_4
- 4: (R+2*G+B) / 4

Copyright © 2026 Texas Instruments Incorporated

The histogram module downsamples the image in the horizontal direction by a factor of 2 using simple averaging filter. This ensures that the memory access requirements of the module are limited to 1 read + 1 write access every 2 cycles (1 access/cycle) and thus can be achieved using a simple memory architecture.

The histogram module requires a ping-pong memory which is mapped to the configuration bus. This allows for histogram operation to run in concurrent with the Read operation from the host. For ease of software complexity, both the Ping/Pong memories map to the same address and it is the responsibility of the design to ensure that the muxing logic always take care of the correct access from both the host and the module. To detect error conditions, if the host is not able to read fast enough from the memory, an error interrupt should be generated whenever the host has initiated a read transfer from the first location of the memory but has not initiated a read transfer from the last location of the memory.

The Histogram module has 2 banks of memores each of 256x20 bits which are used in ping pong fashion. The input pixel has to be downshifted to match the bin size. The Histogram module has separate registers for creating an ROI using horizontal/vertical start postions as well as horizontal/vertical size.

Typically the ROI registers (VISS_FCP_FCC_CFG_HIST_1 and VISS_FCP_FCC_CFG_HIST_2) have to be set that at least one line is skipped for histogram calculation. The one line of time can be used by the histogram module to set the value of each of the bins to zero. This also puts a constraint on the histogram ROI to have a minmum width of 256 pixels.

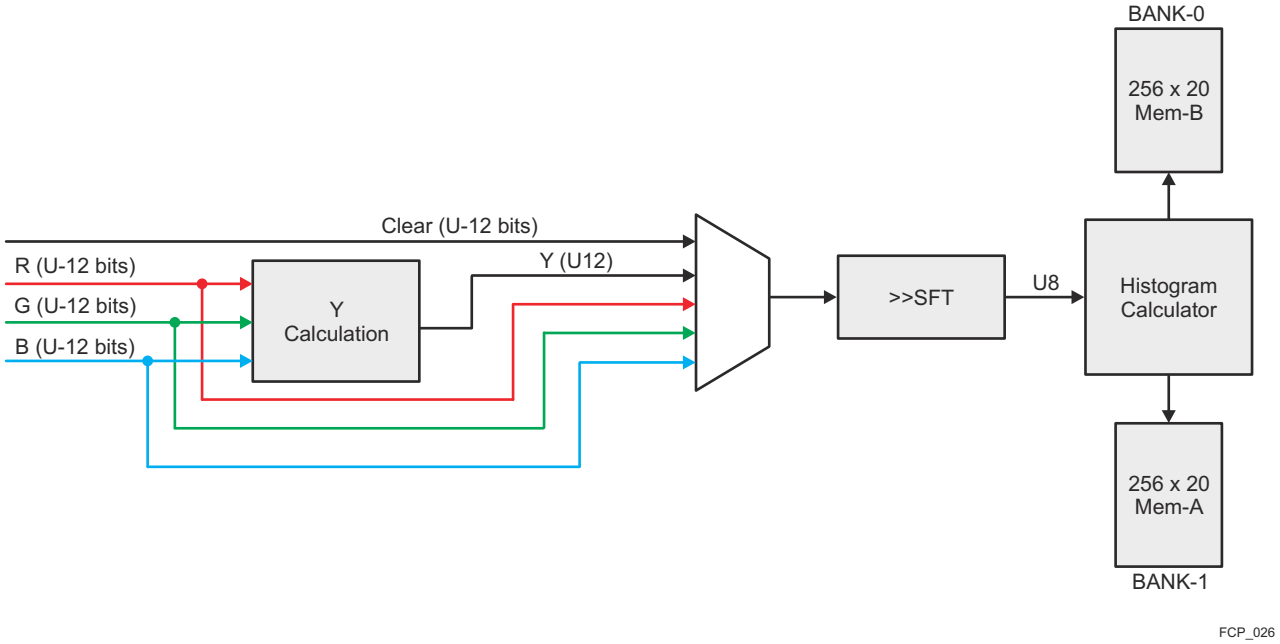

Figure 7-77. Histogram Module

7.7.3.8.3.3.5 Contrast Stretch / Gamma

The logic of the Contrast/Gamma unit is based on the same as that of the 12-8 bit conversion LUTs. There are 3 copies of the logic, one for each color channel. The standard data flow allows for a 12 bit input and 12 bit unsigned output, however different bit width combinations are possible using the select bit of the LUT and the clip value. Each entry of the LUT table is 12 bits.

Figure 7-78 and Figure 7-79 show the block diagram and implementation of linear interpolation for the Contrast Stretch/Gamma module.

Copyright © 2026 Texas Instruments Incorporated

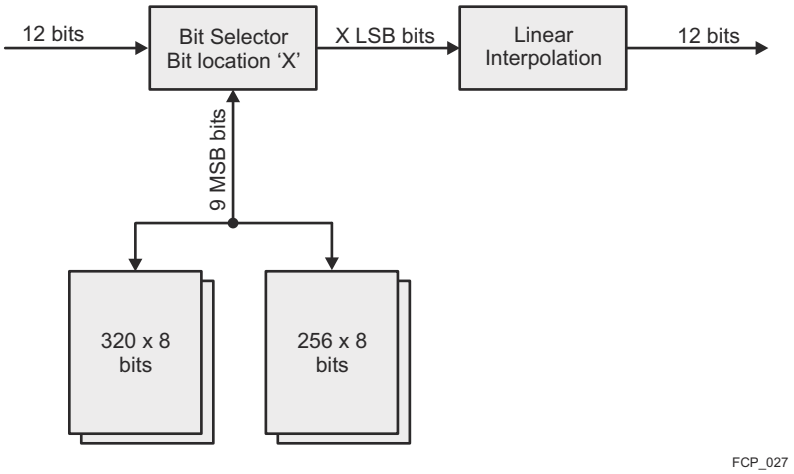

Figure 7-78. Contrast Enhancement Module

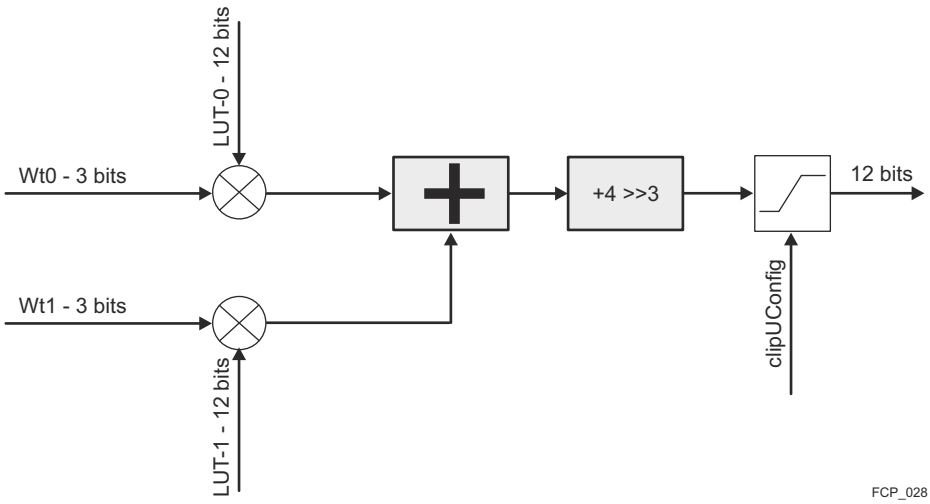

Figure 7-79. Contrast Enhancement Linera Interpolation

The code below shows the LUT addressing scheme which is similar to the 12-8 bit conversion module. The configurable clip at the end of processing allows for less than 12 bit output to be supported directly from the module.

Contrast Enhancement, LUT Addressing

```
CASE BIT_SEL
0 (12 bit data): Addr = Inp[3:11]; Wt1 = Inp[2:0]
1 (11 bit data): Addr = Inp[2:10]; Wt1 = Inp[1:0] & '0'
2 (10 bit data): Addr = Inp[1:9]; Wt1 = Inp[0] & '00'
3 (9 bit data): Addr = Inp[0:8]; Wt1 = '000'
4 (8 bit data): Addr = Inp[0:7]; Wt1 = '000';
//Wt0 is always calculated at 8 - Wt1
Wt0 = 8 - Wt1
```

7.7.3.8.3.3.6 RGB-YUV Conversion

The RGB-YUV conversion is a matrix based conversion from 12-bit RGB to 12-bit YUV. The output after conversion is YUV444.

The conversion is carried out using the equation on Figure 7-80.

Copyright © 2026 Texas Instruments Incorporated

$$Y(x,y) = WRY \times R(x,y) + WGY \times G(x,y) + WBY \times B(x,y) + Offset_1$$
$$Cb(x,y) = WRCb \times R(x,y) + WGCb \times G(x,y) + WBCb \times B(x,y) + Offset_2$$
$$Cr(x,y) = WRCr \times R(x,y) + WGCr \times G(x,y) + WBCr \times B(x,y) + Offset_3_$$

Figure 7-80. RGB-to-YUV Conversion

In this equation, the weights are signed 12 bits (S12Q8) with 8 bit of fraction precision, representing a range of -8 to +7.996. The offsets are signed 13 bits.

Figure 7-81 shows the implementation of the RGB to YUV module. The output after conversion is YUV444, as such it is followed by a chroma downsampling stage where in the Chroma resolution is reduced by half in both the horizontal and vertical direction.

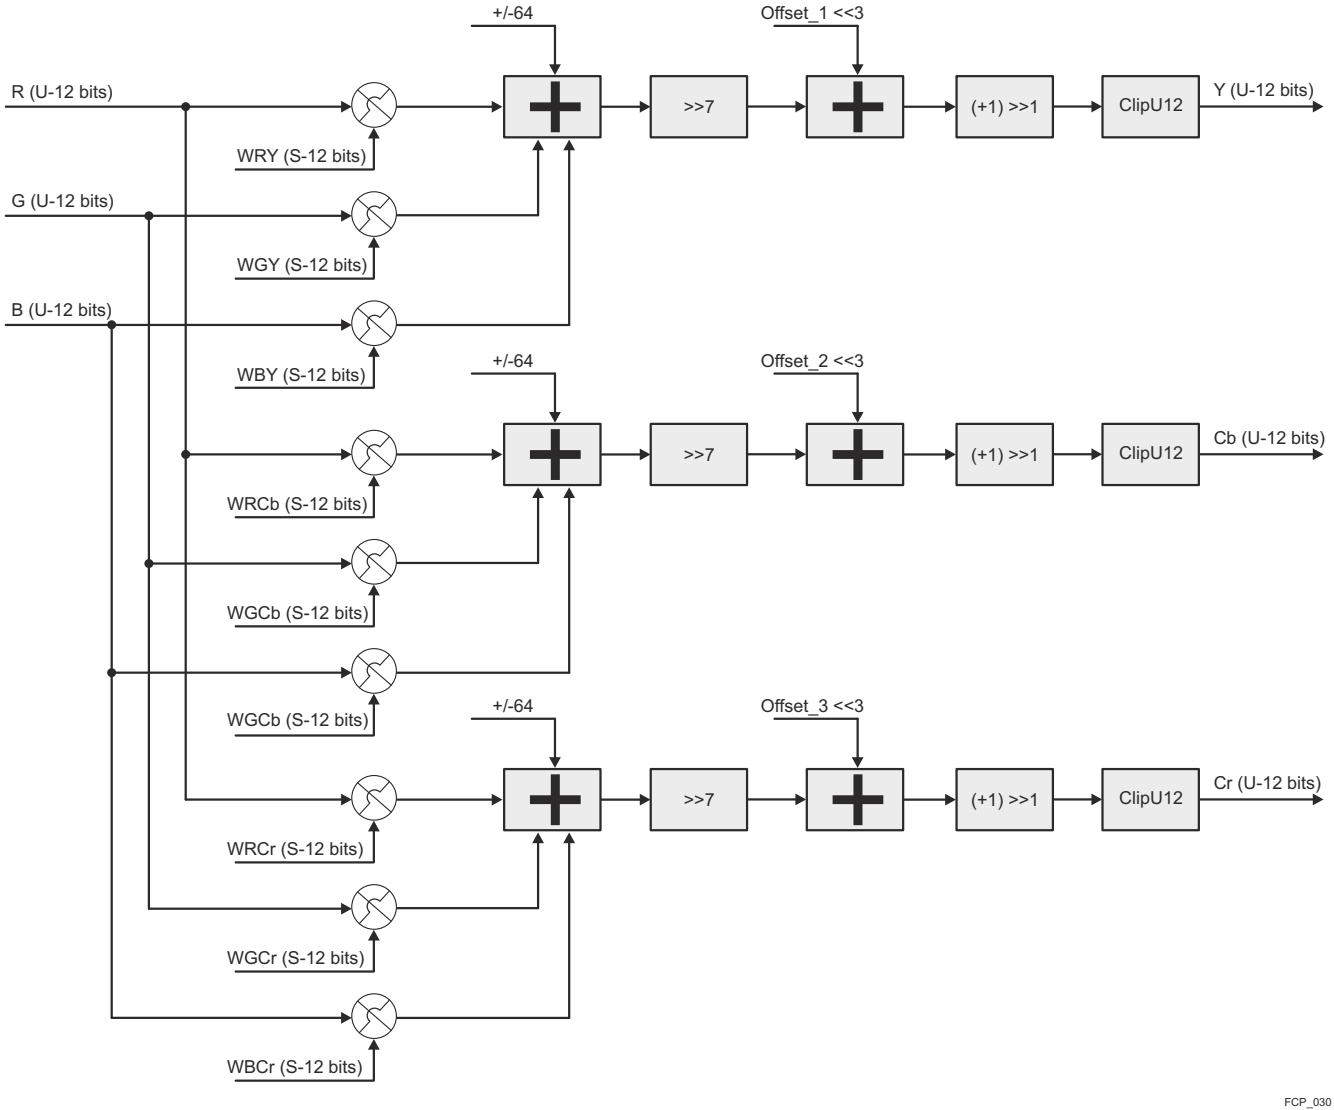

Figure 7-81. RGB to YUV

Copyright © 2026 Texas Instruments Incorporated

7.7.3.8.3.4 444-422/420 Chroma Down-sampler

This module down-samples the chroma components from 444-420 format; effectively reducing the chroma resolution to 50% in both the horizontal and vertical direction.

The downsampling is performed using a 3 Tap fitering [1 2 1] followed by decimation. The conversion logic generates chroma in co-sited/co-located format in both the horizontal and vertical direction.

Figure 7-82 shows the block diagram of the format conversion module. The Chorma output can be optionally downshifted from 12 bits to 8 bits using the LUT/SFT module. Only one copy of the Horizontal averaging filter is required since there is a decimation step following the filtering. Only even locations of both Cb/Cr are retained while the odd locations are decimated, however from design perspective the Hz Averager module works on Cb on even cycles and Cr on odd cycles.

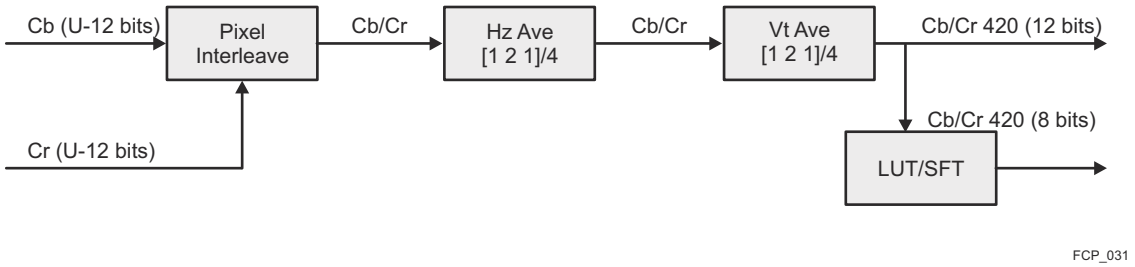

Figure 7-82. 444 to 420 Module

Additionally another mode of operation is to support planar YUV422 mode. In this case the chroma is only downsampled in the horizontal direction and the vertical averaging/downsampling is disabled.

The mode is referred to pseudo 422 since actual 422 mode requires the data to be interleaved between the Y and the chroma channels. In this case the interleaving of Y & C is handled by LSE whereas the Flexible CC module will only generate Y & Cb/Cr (interleaved) planes separately.

7.7.3.8.4 FCP Interrupts

The FCP module has three interrupts, as it follows:

- LUT_CFG_ERR - 16-12 LUT is written during active window
- CFA_PIX_ERR - Access to line memories by CFG during active window
- CFA_MMR_ERR - Non-Shadowed registers are written during active window

There are two additional events:

- SOL_EVENT - Start of line processing for Flexible CFA, triggered when the line enters the Flexible CFA
- SOF_EVENT - Start of frame processing for Flexible CFA, triggered when the frame enters the Flexible CFA

For information about the FCP interrupt events, see Section *VISS Top Level Functional Description*.

7.7.3.8.5 FCP Programmer's Guide

7.7.3.8.5.1 HWA Core Programming Details

The following fields should be programmed correctly for the FCP module to function.

- Input LUT
  - Use the LUT to reduce the bitwidth of the data to 12 bits so that it can pass through the Flexible CFA pipe.
  - If the GLBCE module is disabled, set the bit width and enable the LUT.
- Flexible CFA
  - Program the Flexible CFA kernels based on the input data pettern. Program only 3 channels for Bayer sensors and up to 4 for other non-standard formats like RGB-IR.
  - Set up the correct thresholds (use only one set for Bayer type sensors and two sets for non-standard formats like RGB-IR).
- Flexible CC
  - Set up the Flexible CC for either visual or analytics data flow.

Copyright © 2026 Texas Instruments Incorporated

- For visual, program the CCM-1 to be used as RGB2RGB and Contrast to be used as Gamma with clip at 10 bits. Only the 8-bit outputs are used and the Y8/C8 data is generated using shift down from 10 to 8 (instead of LUT).
- For analytics, CCM-1 is progrmmed depending on sensor input format and the hisogram is used to populate the contrast table. 12-bit outputs are used however Y8/C8 can be generated using 12 to 8 LUT based downshifting. The correct Saturation generation parameters should also be set.

7.7.3.9 VISS Edge Enhancer (EE)

This section describes the Edge Enhancer module.

7.7.3.9.1 Edge Enhancer Introduction

The Edge Enhancer module is used to enhance the visual quality of the image by increasing the sharpness of the image. The module only works on Y (Luma) data and uses a combination of 2D HPF (High-Pass Filter) filtering to detect edges and then apply them on the input image.

The Edge Enhancer consists of two separate blocks internally, the edge enhancer filter and the edge sharpener filter. The module can be programmed to either select the output of one of the filters or to use a blend of both.

Figure 7-83 below shows a conceptual block diagram of the edge enhancer filter. The input data is assumed to be a 12 bits/pixel. The EE module is tuned to process 8-bit images (MSB aligned) but has support to process 10-bit and 12-bit images as well.

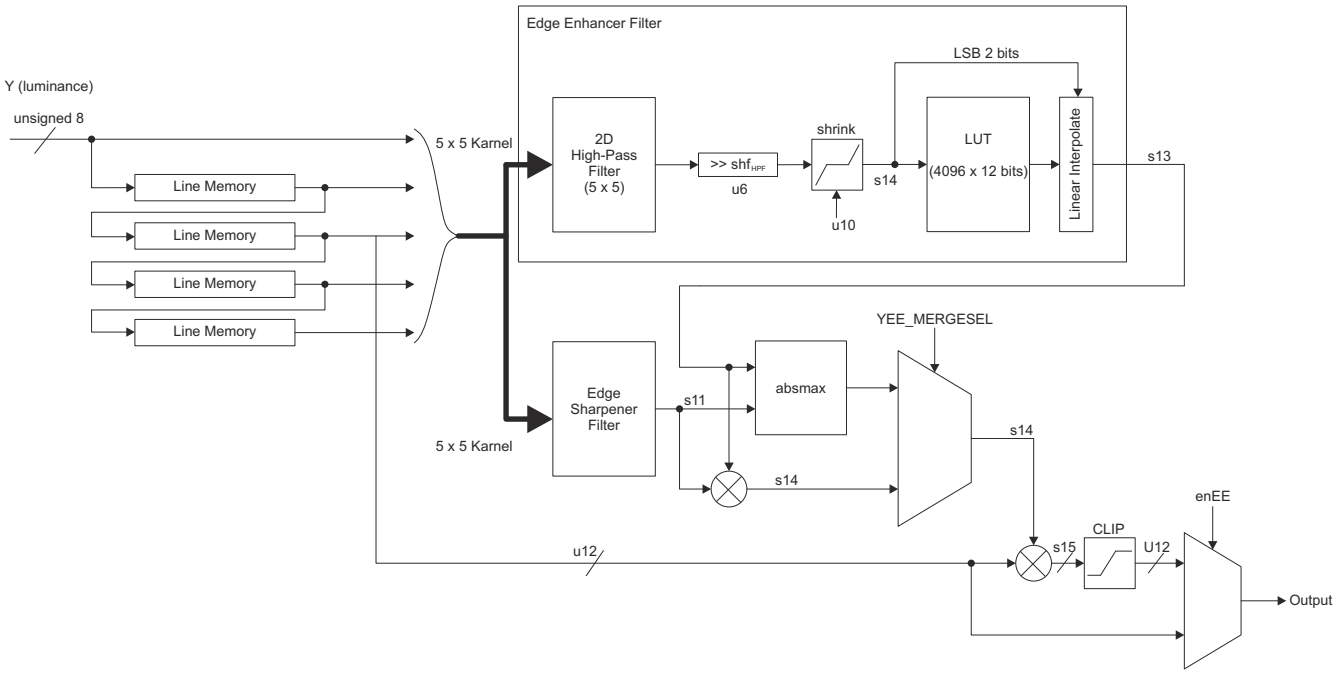

Figure 7-83. Edge Enhancer Block Diagram

7.7.3.9.1.1 Edge Enhancer Filter

The edge enhancer filter works on a 5 × 5 HPF filter (M) with programmable coefficients. The filter is symmetric as such only 3 × 3 coefficients are programmable.

Here, M is a 5 × 5 matrix with programmable coefficients specified by VISS_FCP_EE_YEE_COEF_Ri_Cj (i and j are 0, 1, or 2). The shift value (shf_{HPF}) is specified by VISS_FCP_EE_YEE_SHIFT[5-0] YEE_SHIFT.

Copyright © 2026 Texas Instruments Incorporated

$$HPF(h,v)=\left(\sum_{j=-2}^{2}\sum_{i=-2}^{2}M_{i,j}Y(h+i,v+j)\right)>>shf_{HPF}$$

$$M=\begin{pmatrix} M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,0} & M_{1,0} & M_{0,0} & M_{1,0} & M_{2,0} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \end{pmatrix}$$

Figure 7-84. Edge Enhancer Linear Filter

The HPF value is shrink by a threshold value, $threshold_{HPF}$ (u6 = 10), specified by VISS_FCP_EE_YEE_E_THR register, and clipped to signed 14 bits to get the index for the LUT. The MSB 12 bits of the index are used for the LUT address (4k locations) whereas the LSB 2 bits acts as weight to the linear interpolation logic.

$$index=\text{clip}(\text{shrink}(HPF,threshold_{HPF}),-8k,8k)$$

$$\text{shrink}(x,threshold)=\begin{cases} x+threshold & x<-threshold \\ 0 & -threshold\le x\le threshold \\ x-threshold & threshold<x \end{cases}$$

$$\text{clip}(x,limit_{LOW},limit_{HIGH})=\begin{cases} -limit_{LOW} & x<-limit_{LOW} \\ x & -limit_{LOW}\le x\le limit_{HIGH} \\ limit_{HIGH} & limit_{HIGH}<x \end{cases}$$

Figure 7-85. Edge Enhancer Indexing

The edge enhancement intensity is looked up from the LUT, where A is the MSB 12 bits of the index.

$$E_{\text{int}}=Interpolate(LUT[A],LUT[A+1])$$

Figure 7-86. Edge Intensity LUT Formula

The 5 × 5 HPF filter is not fully programmable, rather only the top left quadrant is programmable coefficients. The rest of the kernel is symmetric along the y and the x axis.

Figure 7-87 below depicts how the kernels are implemented, with the kernel locations marked inside the boxes. The green color shows the kernels that are programmable.

Copyright © 2026 Texas Instruments Incorporated

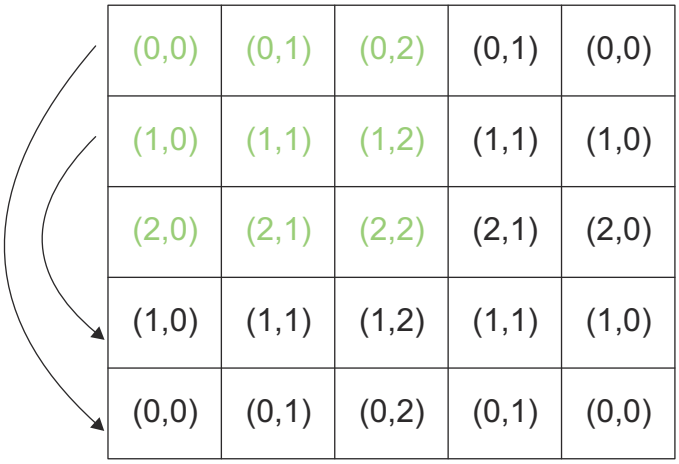

Figure 7-87. 5 × 5 HPF Filter

The border conditions are handled by data duplication on each of the borders when the desired pixel go out of range.

The output of the LUT is the final output of the edge enhancer filter.

7.7.3.9.1.2 Edge Sharpener Filter

Figure 7-88 below shows a high level block diagram of the edge sharpener function.

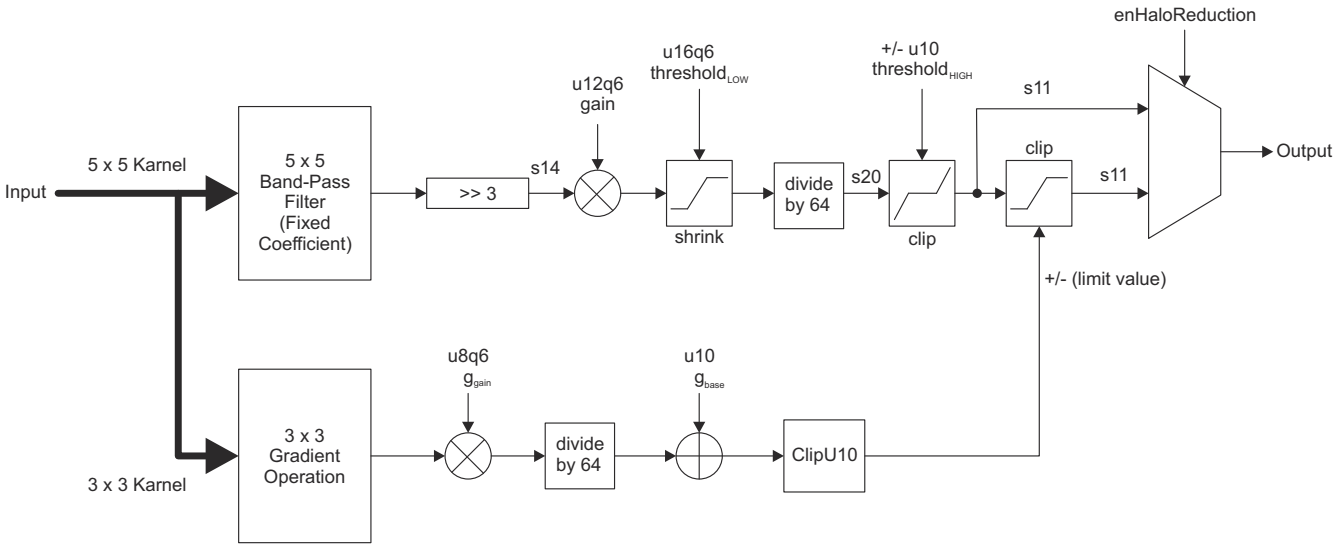

Figure 7-88. Edge Sharpener Function

In edge sharpener filter module, enabled when VISS_FCP_EE_YEE_MERGESEL[0] YEE_MERGESEL = 1, edge clarity is enhanced without producing a halo artifact. In this module, edge intensity is derived by the following 2D linear filter with fixed coefficients shown in Figure 7-89.

Copyright © 2026 Texas Instruments Incorporated

$$S_{i,j} = \begin{pmatrix} 0 & -1 & -2 & -1 & 0 \\ -1 & 0 & 2 & 0 & -1 \\ -2 & 2 & 8 & 2 & -2 \\ -1 & 0 & 2 & 0 & -1 \\ 0 & -1 & -2 & -1 & 0 \end{pmatrix}$$

$$sharpness(h,v) = \text{clip}\left(\text{shrink}\left(g \times \left(\left(\sum_{j=-2}^{2} \sum_{i=-2}^{2} S_{i,j} Y(h+i, v+j) \right) >> 3 \right), threshold_{LOW} \right) >> 6, -threshold_{HIGH}, threshold_{HIGH} \right)$$

Figure 7-89. Edge Sharpener Details

The gain (*g*) and threshold values for shrink/clip function (*threshold* $_{LOW}$, *threshold* $_{HIGH}$) are determined by register values (VISS_FCP_EE_YES_E_GAIN, VISS_FCP_EE_YES_E_THR1, VISS_FCP_EE_YES_E_THR2). The precision of *g* is in U12Q6, *threshold* $_{LOW}$ is in U16Q6 and that of *threshold* $_{HIGH}$ is in U10.

This edge intensity is then clipped by a threshold value in the formula shown in Figure 7-90.

$$S_{\text{int}} = \begin{cases} clip(sharpness, -grad, grad) & \text{Halo reduction on} \\ sharpness & \text{Halo reduction off} \end{cases}$$

Figure 7-90. Edge Intensity Clipping Formula

The threshold value (grad) is a function of the activity around the target pixel, which is derived from gradient values. Gain (g_{grad}) and offset (g_{base}) are specified by VISS_FCP_EE_YES_G_GAIN and VISS_FCP_EE_YES_G_OFT.

$$grad = g_{grad}\left(\min(gx_L, gx_R) + \min(gy_T, gy_B)\right) >> 6 + g_{base}$$

$$gx_L = abs\left(\sum_{j=-1}^{1} \sum_{i=-1}^{1} G_{xL}(i,j) \cdot y(h+i, v+j) \right)$$

$$gx_R = abs\left(\sum_{j=-1}^{1} \sum_{i=-1}^{1} G_{xR}(i,j) \cdot y(h+i, v+j) \right)$$

$$gy_T = abs\left(\sum_{j=-1}^{1} \sum_{i=-1}^{1} G_{yT}(i,j) \cdot y(h+i, v+j) \right)$$

$$gy_B = abs\left(\sum_{j=-1}^{1} \sum_{i=-1}^{1} G_{yB}(i,j) \cdot y(h+i, v+j) \right)$$

$$GxL = \frac{1}{4}\begin{pmatrix} 1 & -1 & 0 \\ 2 & -2 & 0 \\ 1 & -1 & 0 \end{pmatrix}$$

$$GxR = \frac{1}{4}\begin{pmatrix} 0 & 1 & -1 \\ 0 & 2 & -2 \\ 0 & 1 & -1 \end{pmatrix}$$

$$GyT = \frac{1}{4}\begin{pmatrix} 1 & 2 & 1 \\ -1 & -2 & -1 \\ 0 & 0 & 0 \end{pmatrix}$$

$$GyB = \frac{1}{4}\begin{pmatrix} 0 & 0 & 0 \\ 1 & 2 & 1 \\ -1 & -2 & -1 \end{pmatrix}$$

Figure 7-91. Edge Threshold Value Formula

Capping with gradient value prevents overly enhancing edges, and suppresses halo artifacts around edges.

Copyright © 2026 Texas Instruments Incorporated

7.7.3.9.1.3 Merge Block

The output from edge enhancer filter and edge sharpener filter are merged with the following function.

$$E_{merge} = \begin{cases} E_{\text{int}} + S_{\text{int}} & VISS_FCP_EE_YEE_MERGESEL[0]YEE_MERGESEL = 0 \\ \text{absmax}(E_{\text{int}}, S_{\text{int}}) & VISS_FCP_EE_YEE_MERGESEL[0]YEE_MERGESEL = 1 \end{cases}$$

$$\text{absmax}(x, y) = \begin{cases} x & abs(y) \le abs(x) \\ y & otherwise \end{cases}$$

Figure 7-92. Edge Enhancer and Sharpener Merger Formula

The E_{merge} value is added to the Y input value to make the final output.

The contribution of each of the filters can be modified. The edge sharpener filter block can be turned off or reduced in strength using the gain fields. The edge enhancer filter block can be disabled using the LUT.

7.7.4 VPAC Lens Distortion Correction (LDC) Module

This section describes the Lens Distortion Correction (LDC) module.

7.7.4.1 LDC Overview

The LDC module deals with lens geometric distortion issues in the camera system. The distortion can be common optical distortions, such as barrel, pin-cushion, or fisheye distortion. LDC is not limited to just these types of distortions. Affine transformation support is also added to support the image and video stabilization application, where multiple images of the same scene need to be aligned. Perspective warp is an extension to affine transform and offers additional capabilities. Perspective transformations can align two images that are captured from different camera viewpoints or locations. This can also be used to rectify the left and right images of a stereo camera to reduce the complexity of a disparity computation. Perspective transformations can also generate new viewpoints.

7.7.4.1.1 LDC Features

- Autonomous memory-to-memory operation
  - Tile based processing
- Generic mesh based distortion model to correct multiple distortion types
- Perspective warp transformation for perspective correction; affine transform is a subset of perspective warp and supports scaling and rotation
- Support multiple input and output YUV data formats:
  - Among the supported data formats are UYVY (YCbCr 422), NV12 (YCbCr 420) and NV21 (YCbCr 420)
- Support up to 8192 x 8192 image dimension
- Pixel Interpolation
  - Bi-cubic interpolation for Y and bilinear interpolation for Cb/Cr
  - Bilinear interpolation mode to offer double throughput
- Performance
  - 1 cyc/pixel (bilinear)
  - 2 cyc/pixel (Bi-cubic)
- Support to process either Luma only or Chroma only modes in YUV420 input data format to save bandwidth
- Support for independent block size in multiple regions (up to 9 regions)
- Dual output channels for programmable output pixel size
- ECC support on Mesh Data internal storage memories and width conversion LUTs on dual output channel
- Interface to HTS module for block level synchronization with other IPs
- Circular addressing support for Output Write (for SL2 interface) and Input Read
- Event for Block/Frame completion and Error scenarios

7.7.4.2 LDC Functional Description

7.7.4.2.1 LDC Block Diagram

Most digital cameras suffer from some degree of nonlinear geometric distortion. A spatial transformation is required to correct the distortion. In automotive applications, cameras use wide angle lenses, including fisheye lenses to provide 180+° field of view. To visually present the scene to the user in an easy-to-consume representation, these distortions need to be corrected

Back mapping gives coordinates of the distorted image as a function of coordinates of the undistorted output image. Correction involves back-mapping each output pixel to a location in the source distorted image, and thus the corrected image is fully populated. As the distorted pixel locations mostly fall onto fractional coordinates, correction involves interpolation.

As shown in Figure 7-93, the LDC consists of a back mapping block, a x/y offset table, image buffer interface, buffer, an interpolation block, and SL2 interface.

Figure 7-93 is a block diagram of the LDC.

Copyright © 2026 Texas Instruments Incorporated

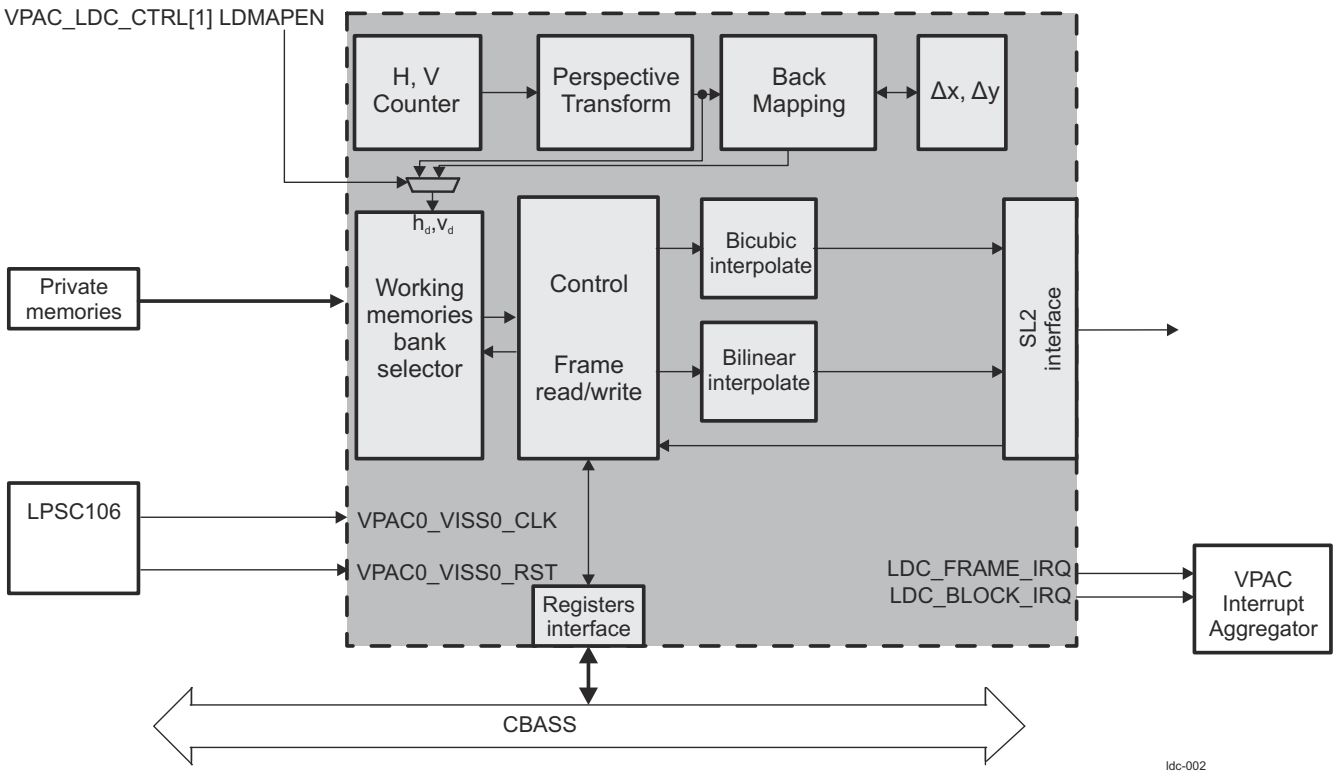

Figure 7-93. LDC Block Diagram

Given the coordinates of the undistorted image, the corresponding coordinates of the distorted image are calculated by combining the output coordinates and the offsets from the offset table. Distorted pixels are read from the image buffer, and buffered for the bilinear interpolation. After the interpolation, corrected image is written back to the SL2 memory.

The LDC processes the image in small two-dimensional (2D) blocks. The software configures appropriate parameters, then initiates the LDC function by writing to an LDC register. The LDC controls the sequencing through 2D blocks, DMA transfers, and computation to process an entire image autonomously. Interrupt, if enabled, is asserted at the completion of the image.

The LDC write is controlled by HTS at block level.

To start the LDC, software must set the LDC_CORE_CTRL[0] LDC_EN bit to 1. The LDC_CORE_CTRL[2] BUSY bit is a status that reflects LDC activity.

7.7.4.2.2 LDC Clocks

Complete VPAC LDC operates on single clock (that is, VPAC0_LDC0_CLK). Except the signals that are coming from LPSC, all other LDC sub-block clock domains are synchronous to VPAC0_LDC0_CLK.

7.7.4.2.3 LDC Interrupts

LDC generates interrupt events and these are made available to the VPAC. VPAC implements compatible interrupt function via the interrupt aggregator, see chapter Section 7.7.2 *VPAC Subsystem*.

All the interrupts are active high and pulsed for one VPAC0_VISS0_CLK cycle. Following interrupts events are generated. Out of these only ECC interrupt should be treated as real interrupt and others are used as events for the interrupt aggregator at VPAC level.

Table 7-112. LDC Interrupt Events

Interrupt Event	Type	Category	Description

CORR_PULSE	pulse	error	ECC Aggregator correctable error, pulse
CORR_LEVEL	level	error	ECC Aggregator correctable error, level

7.7.4.2.3.1 LDC Interrupt Events Description

7.7.4.2.3.1.1 PIX_IBLK_OUTOFBOUND

Generated when back mapping of block non-corner pixel co-ordinate goes out of the pre-computed input bounding box (i.e. data required for processing is not available in private pixel storage). This event is generated for the first occurrence of error in each frame. Upon this error, PIX_PAD setting needs to be reviewed. Upon pixel out of bound, pixel co-ordinate will be clipped to the pre-fetched block boundary. Usually no special treatment is required on this error event. Only few pixels are expected to be have this condition..

7.7.4.2.3.1.2 MESH_IBLK_OUTOFBOUND

Generated when mesh data required for non-corner mesh co-ordinate goes out of the pre-computed mesh bounding box (i.e. mesh data required for processing is not available in internal mesh storage). This event is generated for the first occurrence of error in each frame. This error condition is handled inside design by clipping the mesh data location to the pre-fetched block boundary. No special treatment is expected on this error event.

7.7.4.2.3.1.3 IFR_OUTOFBOUND

Generated when back mapped input pixel co-ordinate goes out of valid input frame boundary or co-ordinates post Perspective warping goes out of valid Mesh frame size (Frame size for which mesh data is available). This event is generated for the first occurrence of error in each frame. In the event of error condition, design will clip the co-ordinates to valid frame boundary. It is recommended to review the source of the error to make sure that it is expected.

7.7.4.2.3.1.4 INT_SZOVF

Generated when intermediate variables of affine or perspective transform operation goes above what hardware supports (U16Q3). This event is generated for the first occurrence of error in each frame. In the event of error condition, design will clip the variables the size to what HW supports. Upon this error, Affine and Perspective coefficients need to be reviewed.

7.7.4.2.3.1.5 VPAC_LDC_FR_DONE_EVT

Generated on once complete output frame is written into SL2.

Copyright © 2026 Texas Instruments Incorporated

7.7.4.2.3.1.6 VPAC_LDC_SL2_WR_ERR

This event is generated whenever the LDC SL2 Output VBUSM Interface write status is something other than 0 (success).

7.7.4.2.3.1.7 PIX_IBLK_MEMOVF

Generated when input pixel block memory storage requirement is more than internal pixel memory or each side of input block size goes above 1023. This event will be generated once per block in case of error. In the event of error condition, one or more output pixel blocks corruption. Upon this error, Output Block size setting needs to be reviewed.

7.7.4.2.3.1.8 MESH_IBLK_MEMOVF

Generated when Mesh block internal storage requirement is more than internal Mesh memory or either side of input block size goes above 1010. This event will be generated once per block in case of error. In the event of error condition, one or more output pixel blocks corruption. Upon this error, Output Block size or Affine/Pwarp parameters or mesh sub-sampling factor setting needs to be reviewed.

7.7.4.2.3.1.9 VPAC_LDC_VBUSM_RD_ERR

This event is generated whenever the LDC Read VBUSM Interface status is something other than 0 (success).

7.7.4.2.4 LDC Affine Transform

The LDC first performs an affine transform, which can be used for rotations and scaling, as shown in Figure 7-94. The output of the pixel coordinate is used as the input address to the affine transform.

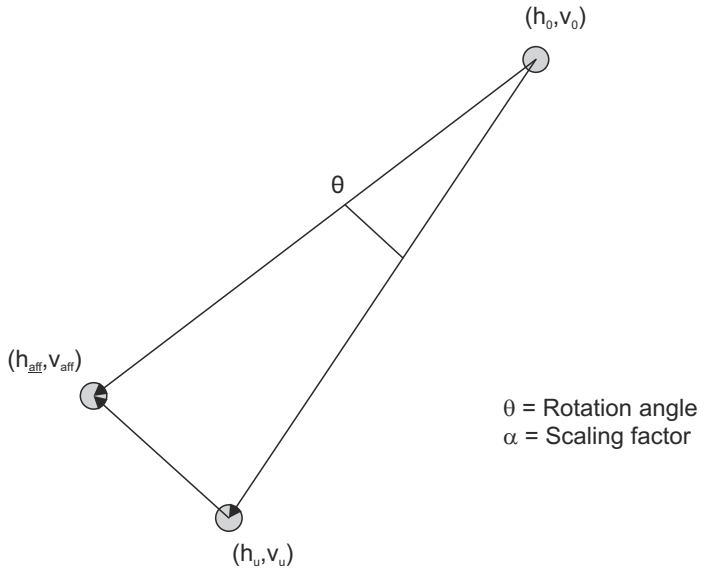

Figure 7-94. LDC Affine Transformation

The mapping from destination coordinate to the source coordinate is expressed as:

$h_{aff} = a \times h_u + b \times v_u + c$

$v_{aff} = d \times h_u + e \times v_u + f$

This transform allows full rotation, expansion, contraction, and translation. The parameters {a, b, d, e} are in S16Q12 (signed number on 14 bits with 2 bits for integer and 12 bits of fraction) format, and parameters {c, f}

Copyright © 2026 Texas Instruments Incorporated

are in S16Q3 format (signed number on 16 bits with 13 bits for integer and 3 bits of fraction). These parameters must be set in following bit fields:

- a = LDC_CORE_AFF_AB[15:0] A
- b = LDC_CORE_AFF_AB[31:16] B
- c = LDC_CORE_AFF_CD[15:0] C
- d = LDC_CORE_AFF_CD[31:16] D
- e = LDC_CORE_AFF_EF[15:0] E
- f = LDC_CORE_AFF_EF[31:16] F

7.7.4.2.5 LDC Perspective Transformation

When a camera is viewing a scene from two different positions or when multiple cameras are viewing the scene from different positions, a transformation between the two viewing angles is needed to align the images. Under specific conditions, the class of geometric transformations known as homography, or planar-perspective transformation, will capture the geometric relationship between the images accurately. Common applications of homography transforms are to align (or stitch) multiple frames of the same scene to compute a panoramic output image. A second application is the alignment of planar surfaces in the world. Finally, perspective transforms are also useful in computing depth maps from a stereo image pair. By rectifying the two views, the search to compute disparity between the two views is simplified to a 1-D search problem. The homography is defined by a 3x3 transformation matrix, as in

$$h_{aff} = a * h_u + b * v_u + c \quad (20)$$

$$v_{aff} = d * h_u + e * v_u + f \quad (21)$$

$$z = \max(0, g * h_u + h * v_u + 1) \quad (22)$$

$$h_p = h_{aff} / z \quad (23)$$

$$v_p = v_{aff} / z. \quad (24)$$

The affine transform is a subset of the perspective transformation. By setting g = h = 0, $h_p = h_{aff}$ and $v_p = v_{aff}$.

In image alignment applications, the homography matrices are computed by locating corresponding points in the two frames and estimating the matrix parameters to transform the set of points in one frame onto the corresponding points in the second frame. In the stereo rectification application, the matrix is determined (pre-computed) at the calibration step and remains fixed.

When LDC is requested to provide a change in the frame size between the input and output, the affine/perspective parameters must be programmed to implement the coordinate scaling (see for programming details). In the following sections, the mesh table is used to program distortion correction. The table sizes are defined based on the total output frame size.

7.7.4.2.6 LDC Lens Distortion Back Mapping

In YCbCr mode, the offset table defines a (x,y) vector for a regular grid of output points. The grid can be fully sampled or down sampled. A fully sampled grid will define an offset vector for every output pixel, defining exactly where to fetch the input data to compute the output pixel. This is the most precise definition and can capture rapidly changing offset tables. The drawback is that it will require a large amount of memory bandwidth as the LDC engine will be reading offset values for every output pixel. Since most offset tables are not expected to change rapidly in a small spatial region, LDC supports reading a subsampled offset table. Offset tables can be subsampled by powers of two in both horizontal and vertical directions and the subsampling factor is set in the register, LDC_CORE_MESHTABLE_CFG[2-0] M. This mode conserves memory bandwidth by reducing the amount of data read to describe the offset vectors, but requires more hardware to interpolate the missing offset vectors. LDC supports bilinear interpolation to interpolate missing offset vectors.

The mapping procedure is described by the following series of equations. Given an output pixel at location, we compute the input pixel location.

Figure 7-95. LDC Lens Distortion Back Mapping Offset Calculation

Graphically, this procedure is shown in Figure 7-96.

Copyright © 2026 Texas Instruments Incorporated

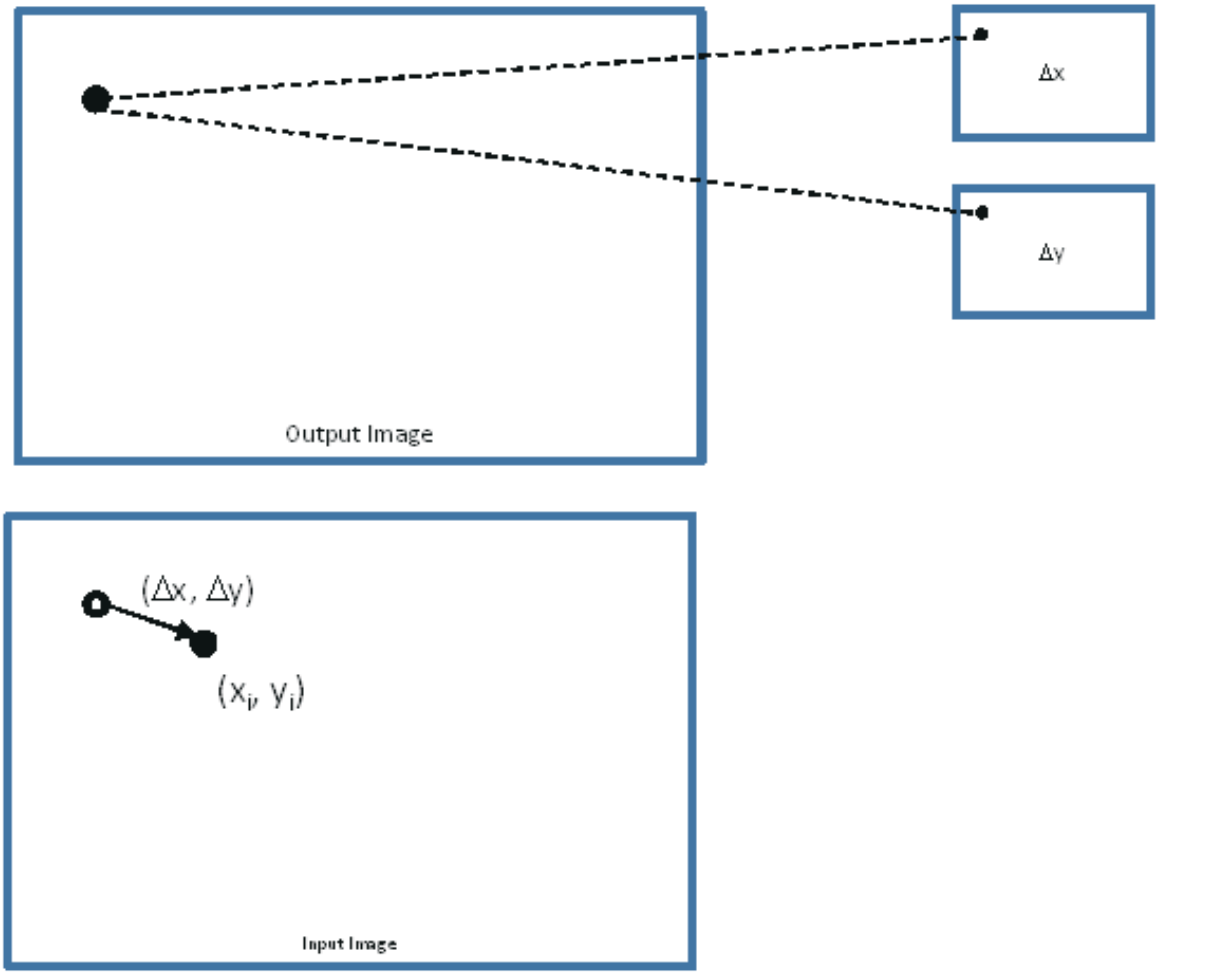

Figure 7-96. LDC Back Mapping Procedure Using Offset Table

The input coordinate (x_i,y_i) refers to final input frame co-ordinates and is used to fetch the appropriate input pixels for interpolation. The interpolation procedure is described in . Before fetching data(x_i,y_i), is clipped to the input frame boundary.

7.7.4.2.6.1 LDC Mesh Table Storage Format

The size of the mesh table is dependent on the Total output frame size. The size must be:

$$\text{Table Width}=\text{CEIL}((\text{Mesh Frame Width})/2^M)+1 \quad (32)$$

$$\text{Table Height}=\text{CEIL}((\text{Mesh Frame Height})/2^M)+1. \quad (33)$$

Mesh frame width and height are specified by registers: LDC_CORE_MESH_FRSZ[13-0] W and LDC_CORE_MESH_FRSZ[29-16] H. The downsampling factor, M, is specified by register LDC_CORE_MESHTABLE_CFG[2] M.

The mesh table should be stored with delta(x) and delta(y) offsets interleaved and stored in raster order. Each offset is S16Q3, so a table entry is 32-bits, including both delta(x) and delta(y). The location of the mesh table is configured by registers LDC_CORE_MESH_BASE_H and LDC_CORE_MESH_BASE_I. The buffer width (>= Table Width), is provided by LDC_CORE_MESH_OFST[15-0] OFST. The mesh table must be aligned on a 16-byte boundary.

.

7.7.4.2.7 LDC Pixel Interpolation

In UYVY and NV12 mode, the pixel interpolation type can be set to bi-cubic interpolation for best quality or bilinear interpolation for faster performance.

As the coordinates (h_d,v_d) calculated by the back-mapping function are not generally integer values, bi-cubic or bilinear interpolation is applied to the distorted pixels.

Depending on register configuration, bi-cubic or bilinear interpolation is used to interpolate the output Y pixels:

- LDC_CORE_CFG[6] YINT_TYP = 0, bi-cubic interpolation for Y, bilinear for other components
- LDC_CORE_CFG[6] YINT_TYP = 1, bi-linear interpolation for all components

In the case of bi-cubic interpolation, the distorted pixel is interpolated from the 16 Y pixels in the 4 x 4 grid around the distorted location, as shown in Figure 7-97. Bi-cubic interpolation is used first along the horizontal direction, then the vertical direction.

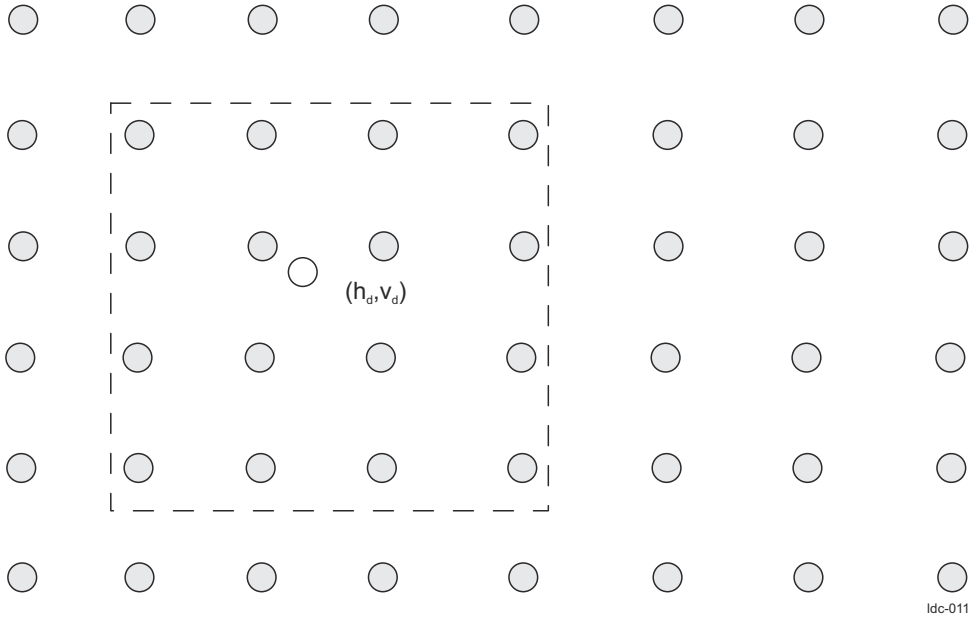

Figure 7-97. LDC Bi-cubic Interpolation for Y

If bi-linear interpolation is selected, the distorted pixel is interpolated from the four Y pixels in the 2 x 2 grid around the distorted location, as shown in Figure 7-98.

Copyright © 2026 Texas Instruments Incorporated

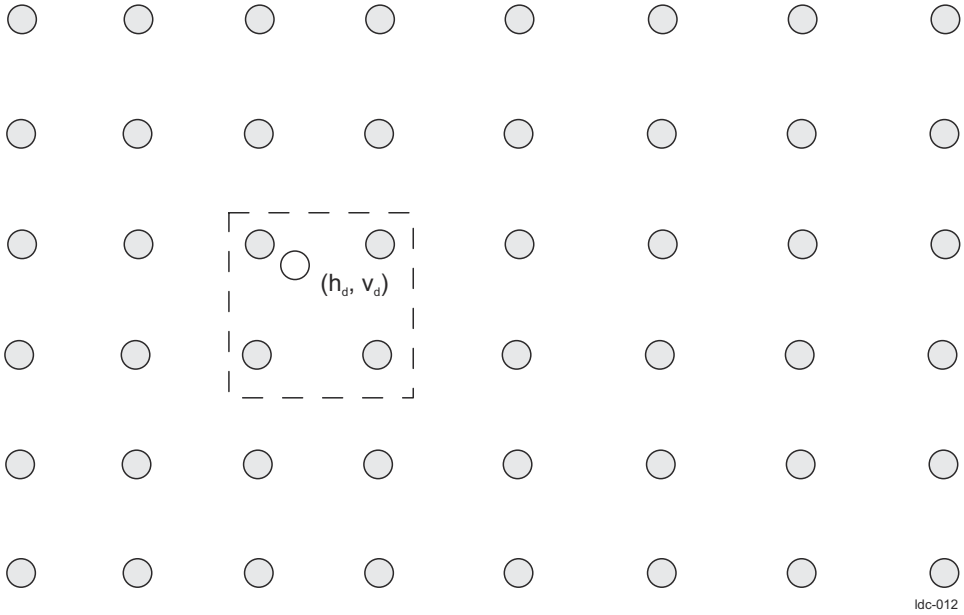

Figure 7-98. LDC Bi-linear Interpolation for Y

For Cb and Cr components, simple bilinear interpolation is used. Each distorted pixel is interpolated from the four same-color pixels on the 2 x 2 grid around the distorted location. For UYVY data, the Cb/Cr grid is not square, but is 2x wider compared to the height. This is shown in Figure 7-99.

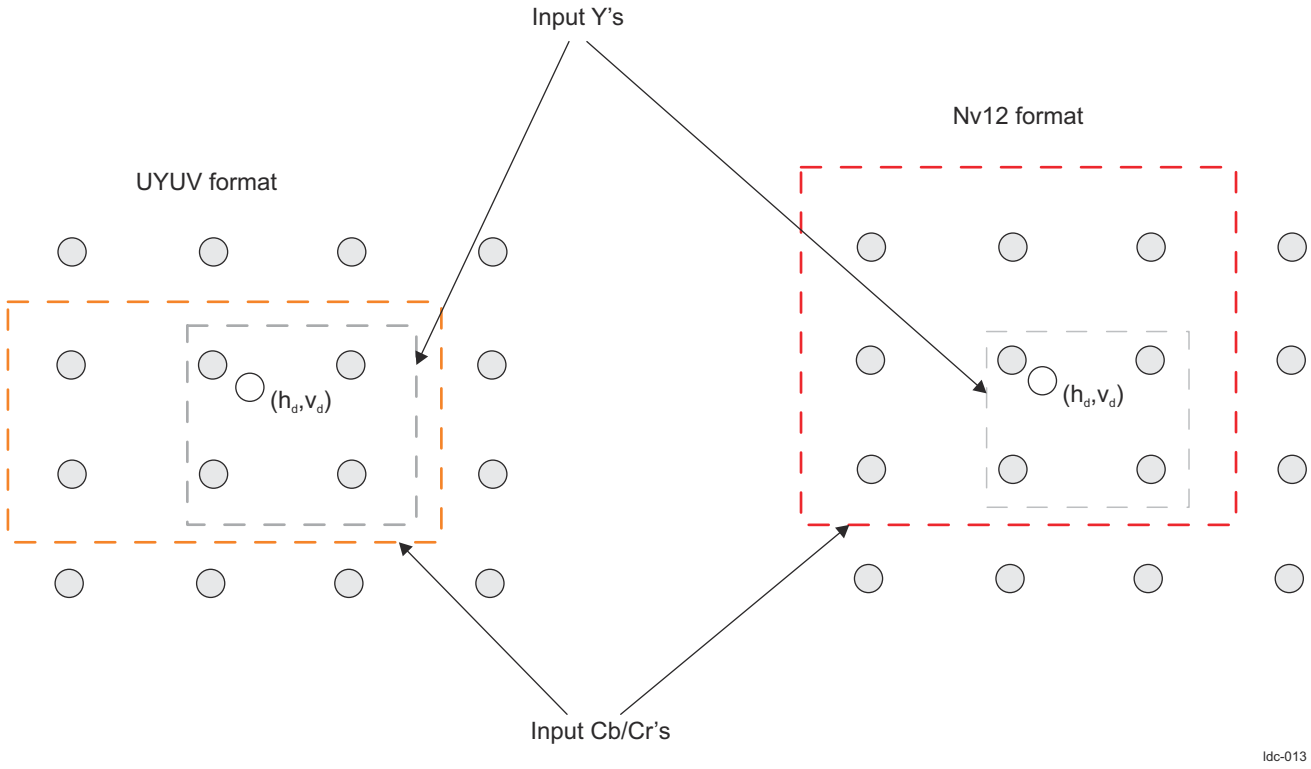

Figure 7-99. LDC Bilinear Interpolation for CB/Cr in UYVY and NV12 Format

7.7.4.2.8 LDC Buffer Management

Nonlinear nature of the Back Mapping suggests 2-D processing to make more efficient use of external memory bandwidth. Since the mapping computation is non-trivial, the hardware requires the software to provide a number of data management parameters to assist hardware with data transfers.

7.7.4.2.8.1 LDC Buffer Management

Once mesh block fetch is completed, final input co-ordinates are calculated by applying back mapping on previously calculated perspective warp corner pixel co-ordinates. Additional padding is applied on top of these back mapped corner co-ordinates based on the interpolation type.

The LDC processes a block of LDC_CORE_OUT_BLKSZ[7:0] OBW x LDC_CORE_OUT_BLKSZ[15:8] OBH (output block width by output block height) pixels at a time in a raster-scan order throughout the image. OBW is constrained to be a multiple of a base width, depending on the operating mode. This is described in Table 7-113. OBH should be even. The LDC uses four corners of the output block plus some padding to fetch the input block. Due to extreme scenarios, there will be scenarios where above bounding box calculated by hardware doesn't cover all the input data required to generate particular output block. To cover those cases, software needs to supply additional PixelPad, the amount of padding in input block in all directions. Software must supply OBW, OBH, and LDC_CORE_OUT_BLKSZ[19:16] PIXPAD, the amount of padding in input pixels. Software must guarantee that, for EVERY output pixel in the OBW x OBH output block, the input pixels required are bounded by back mapping of the four corners plus/minus the padding. More precisely, the input block is determined by:

- IBX_start = min(truncate(distortx(corner1)), truncate(distortx(corner3))) - HwPad - PixelPad
- IBX_end = max(truncate(distortx(corner2)), truncate(distortx(corner4))) + HwPad + PixelPad
- IBY_start = min(truncate(distorty(corner1)), truncate(distorty(corner2))) - HwPad - PixelPad
- IBY_end = maxn(truncate(distorty(corner3)), truncate(distorty(corner4))) + HwPad + PixelPad

where corner1, corner2, corner3, and corner4 are upper-left, upper-right, lower-left, and lower-right corners of the OBW x OBH output block, and distortx(.), distorty(.) are X and Y distorted coordinates of the corners. Distorted coordinates computed by the back-mapping process described in Section 7.7.4.2.6, *LDC Lens Distortion Back-Mapping*. Figure 7-100 shows the input block bound calculation. Table 7-113 lists the OBW requirements.

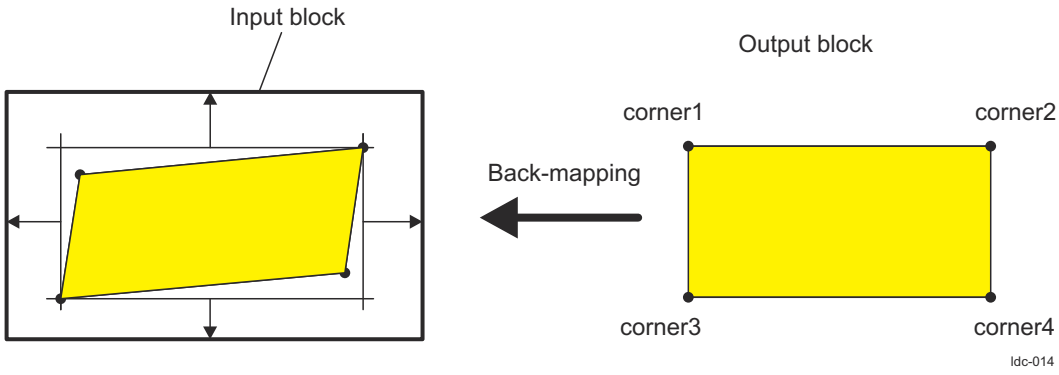

Figure 7-100. LDC Input Block Bound

Table 7-113. LDC OBW Requirements

Data Format	OBW must be a multiple of
YUV422	8
YUV420	8

Typically for geometric distortion, the LDC_BLOCK[19:16] PIXPAD bit field must be 4 to accommodate neighbor sets for all colors. Software must set the PIXPAD bit field correctly.

Copyright © 2026 Texas Instruments Incorporated

OBH and OBW must be large enough for efficient operation of the lens distortion operation. As shown in Table 7-113, OBW is constrained to ensure efficient external memory write. Another constraint is that input block size, (IBX_end – IBX_start + 1) x (IBY_end - IBY_start + 1), for EVERY input block of the image, must fit the allocated input buffer. These parameters must not be specified pessimistically (OBH, OBW too small, or PixelPad too large). Pessimistic parameter setting degrades performance and incurs unnecessary external memory transfer.

The LDC can process a portion of the image, rather than the entire image. This saves time by letting an image process through multiple software/LDC interactions to correct only a portion of the image (See Multi-pass Frame processing).

An intermediate event, *hts_tdone*, is also provided on completion of each macro block output write. This allows the LDC operation to be pipelined with other tasks. The LDC output write stall after this event, waiting for a pulse on the hts_tstart signal to begin writing the next macro block.

7.7.4.2.9 LDC Multi Region with Variable Block size

Distortion in wide angle lenses causes output block size to be very small due to extreme scaling in particular regions of the Image. This could be caused by high field-of-view or viewing position. The range of “Ratio of Output block to input pixel block size” is very high across the frame.

In order to solve this, LDC supports dividing the frame into multiple regions and output block size can be programmed independently for each region. Frame can be divided up to 9 regions. Frame can be divided into maximum of three slices horizontally and maximum of three slices vertically as shown in Figure 7-101. All the regions in a vertical slice share the common horizontal start location and all the regions in a horizontal slice share the common vertical start location. Width of vertical slices can be configured using LDC_CORE_REGN_W12_SZ[13-0] W1, LDC_CORE_REGN_W12_SZ[29-16] W2 and PAC_LDC_REGN_W3_SZ[13-0] W3 register fields. Height of horizontal slices can be configured using LDC_CORE_REGN_H12_SZ[13-0] H1, LDC_CORE_REGN_H12_SZ[29-16] H2 and LDC_CORE_REGN_H3_SZ[13-0] H3 register fields.

Copyright © 2026 Texas Instruments Incorporated

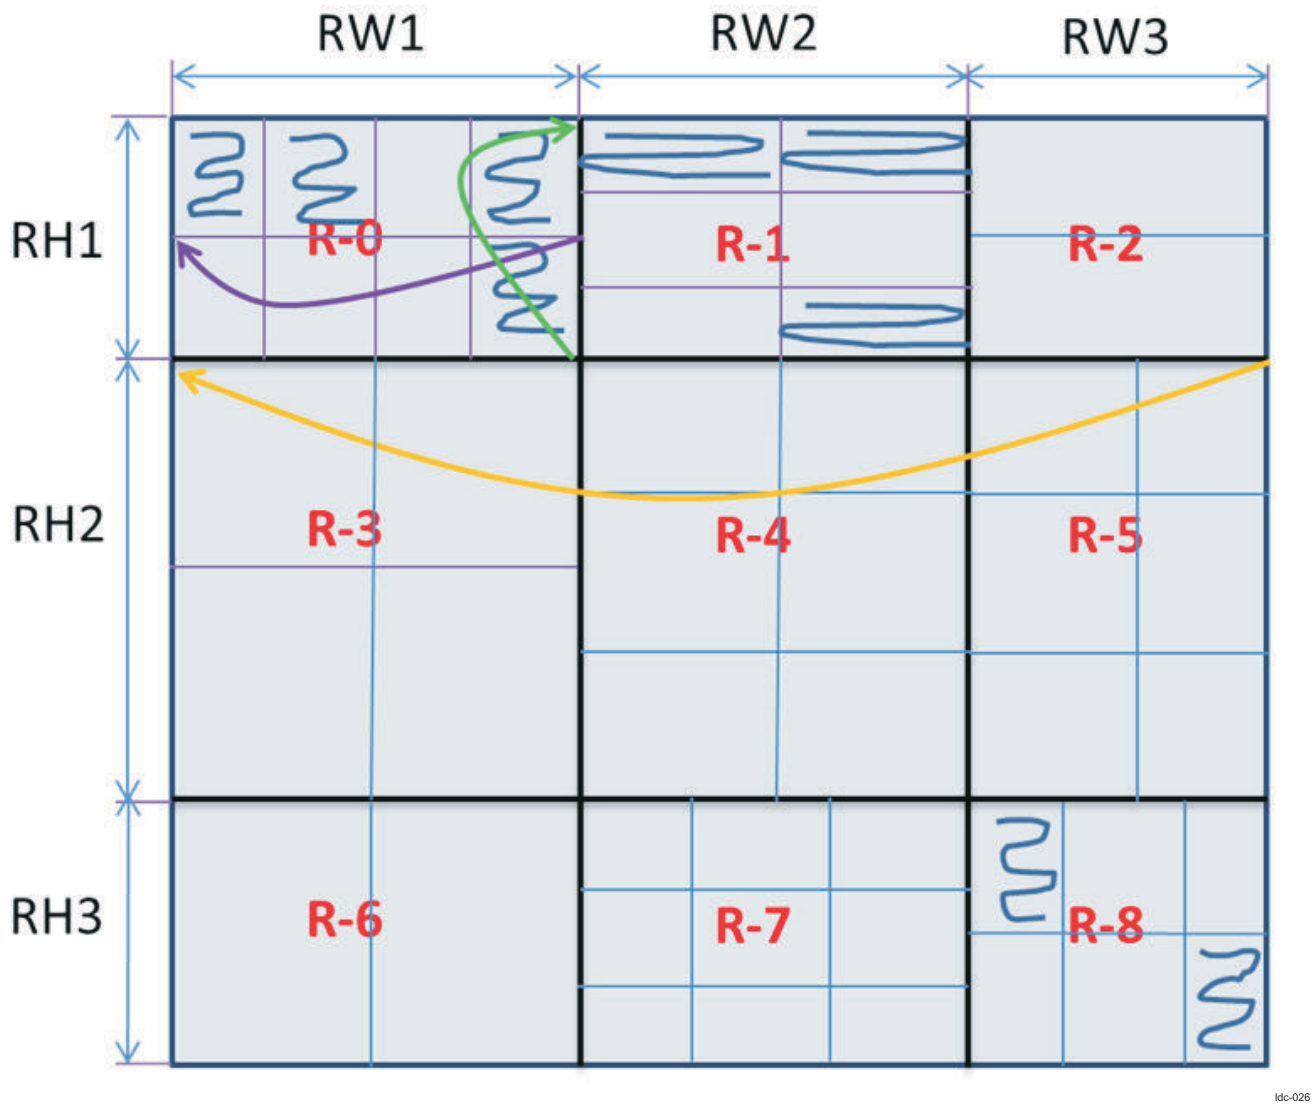

Figure 7-101. LDC Variable Block Size with Multiple Regions

Hardware will process the each region as independent frame, hence processing of the pixels will in 2D sequence with in the region. Up on completing processing of one region, it will process next region in raster direction.

7.7.4.2.9.1 LDC Region Skip Feature

In surround view use case, some regions of the frame won't be used for stitching of final frame. By programming VPAC_LDC_REGION_CTRL_j[0] ENABLE to low, hardware will skip the processing of particular region.

Note

Hardware has to make sure that FRAME_DONE information to LSE is generated on last pixel of last valid region.

As an example shown in Figure 7-102, Region-5, 7 and 8 are skipped for processing. FRAME_DONE is passed on last pixel of Region-6. Ordering and numbering of the regions will remain the same even in the case of skipping some regions.

Copyright © 2026 Texas Instruments Incorporated

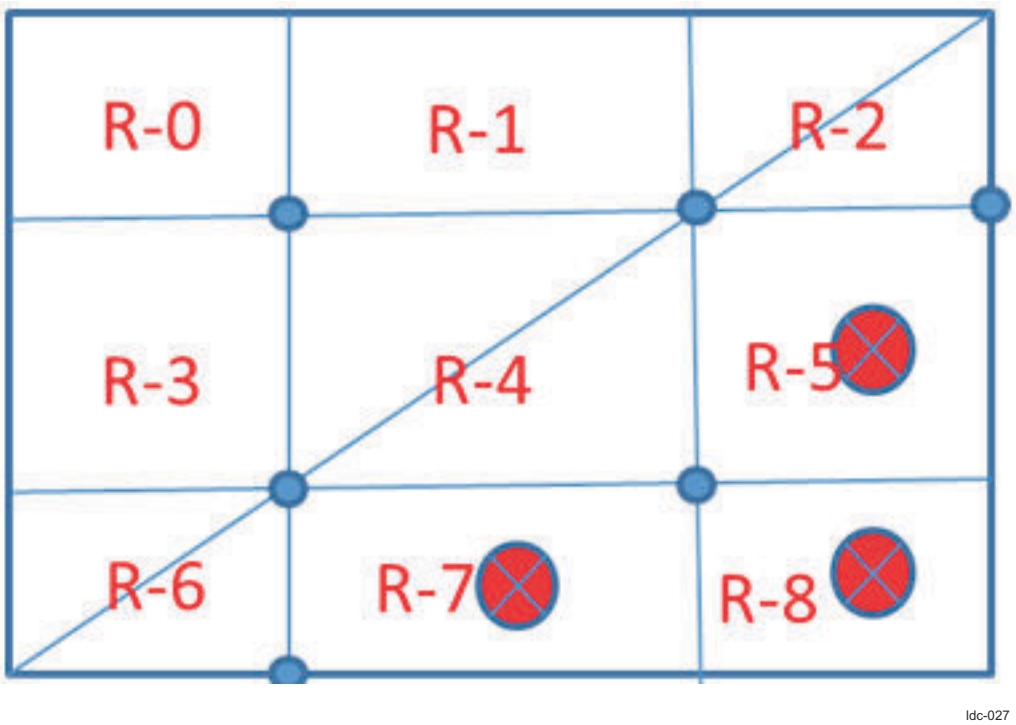

Figure 7-102. LDC Region Skipping Example

7.7.4.2.9.2 LDC Support for sub-set of 3x3 regions

HW supports dividing the frame into sub-set of 3x3 regions. Following combinations of regions are supported.

- 3 vertical slices
  - RW1 = x , RW2 = y and RW3 = z
- 2 vertical slices
  - RW1 = x , RW2 = y and RW3 = 0
  - Last region width has to be zero
- 1 vertical slice
  - RW1 = x , RW2 = 0 and RW3 = 0
  - Last two regions width has to be zero
- 3 horizontal slices
  - RH1 = x , RH2 = y and RH3 = z
- 2 horizontal slices
  - RH1 = x , RH2 = y and RH3 = 0
  - Last region height has to be zero
- 1 horizontal slice
  - RH1 = x , RH2 = 0 and RH3 = 0
  - Last two regions height has to be zero

As shown in Figure 7-103, 2x2 region partitioning can be done by programming RW3=RH3=0.

Note

Region numbering remains as in 3x3 region partitioning with R3, R6-R8 being null regions.

Copyright © 2026 Texas Instruments Incorporated

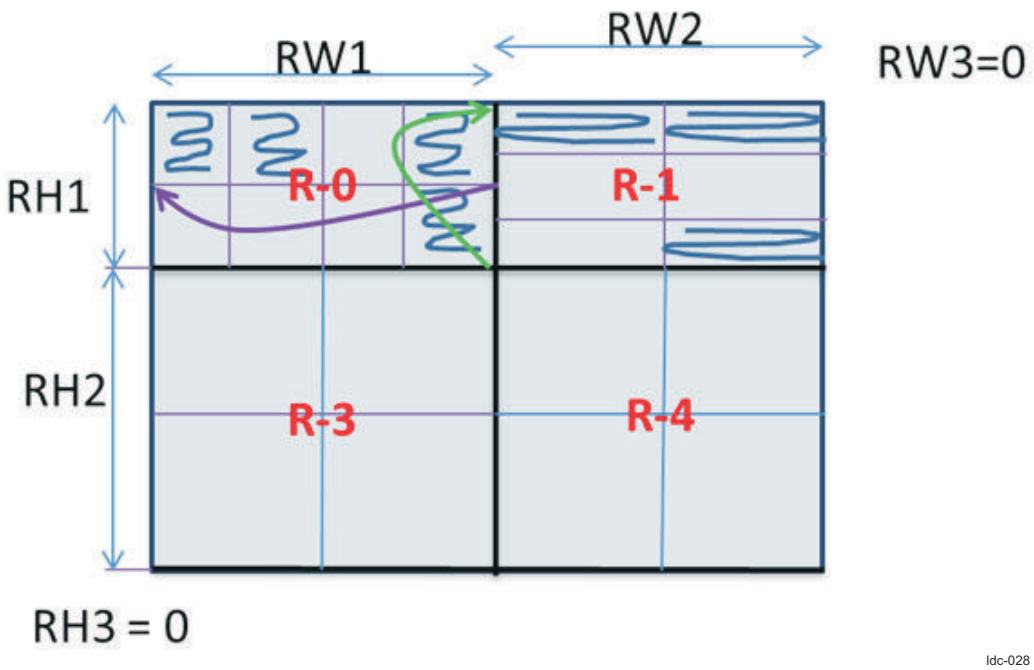

Figure 7-103. LDC 2x2 Region Partitioning Example

7.7.4.2.9.3 LDC Limitations of Multi Region Scheme

Following features can't be supported when multi region processing is enabled.

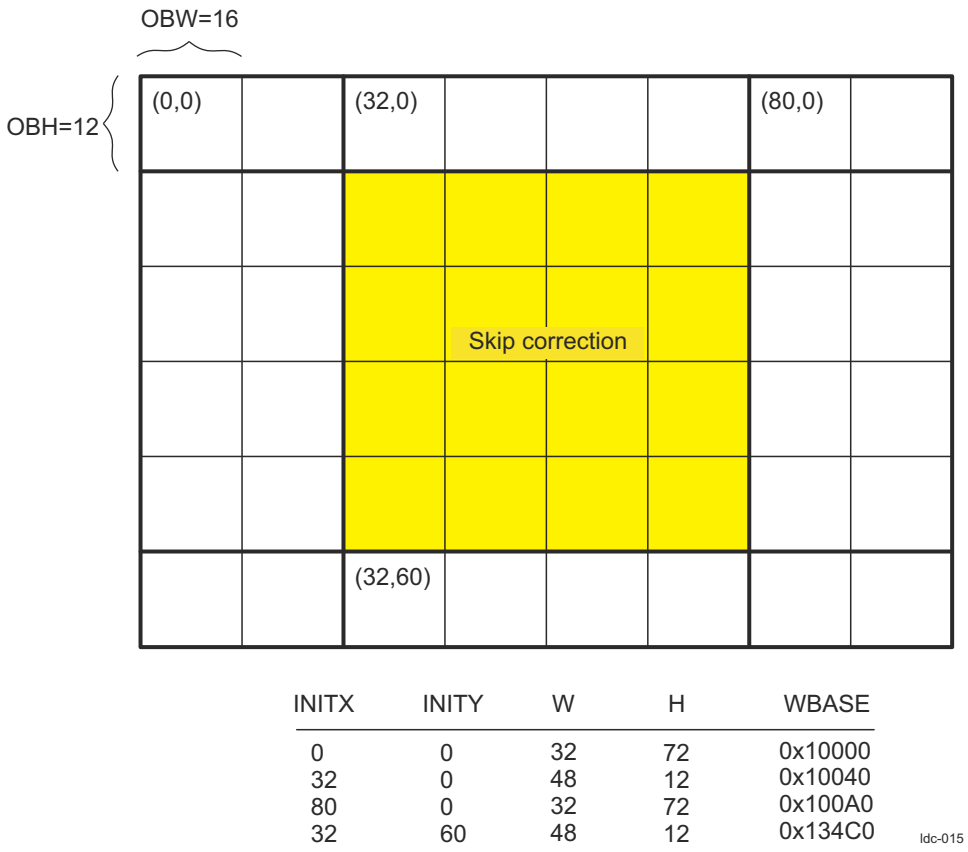
- Circular buffer support can't be enabled on Input data fetch
- HTS synchronization can't be enabled on Input data fetch
- LDC can't be joined with other HWAs in the VPAC. LDC output needs to be written to external memory.
- HTS can't make use of multiple BPR buffers available in SL2 circular buffer

7.7.4.2.9.4 LDC Multi Region Block Constrains

- RW1+RW2+RW3 must be equal to OFW
- RH1+RH2+RH3 must be equal to OFH
- SW to program the LSE buffer Stride, at-least the size of largest output block width among all regions.
- SW to program buffer height at-least twice the maximum block height among all regions

7.7.4.2.10 LDC Multi-pass Frame processing

The LDC can process a portion of the image, rather than the entire image. This saves time by letting an image process through multiple software/LDC interactions to correct only a portion of the image.



An intermediate interrupt can occur after processing each macro block. This lets the LDC operation be pipelined with other tasks.

To process only a portion of the image, the following parameters are required:

- LDC_CORE_INITXY[12:0] INITX: X coordinate of upper-left corner of output frame
- LDC_CORE_INITXY[28:16] INITY: Y coordinate of upper-left corner of output frame
- LDC_CORE_INPUT_FRSZ[13:0] W: Width of output frame
- LDC_CORE_INPUT_FRSZ[29:16] H: Height of output frame
- FrameBase SDRAM address of upper-left corner of output frame (Y and Cb/Cr base needed in case of YCbCr420)
- FrameOfst SDRAM frame width (in bytes)

Figure 7-104 is an example of multiple-pass processing with middle-of-the-image skipped.

INITX	INITY	W	H	WBASE
0	0	32	72	0x10000
32	0	48	12	0x10040
80	0	32	72	0x100A0
32	60	48	12	0x134C0

ldc-015

Figure 7-104. LDC Multiple-Pass Correction Example

The LDC does not copy skipped blocks from the input frame to the output frame (necessary task unless output frame = input frame); software must set up and initiate this memory copy.

A note on in-place operation to conserve external memory: Depending on the offset table and configuration parameters, it may not be feasible to point the output image at the input image and have corrected pixels overwriting the source image. Software must determine whether it is feasible to overwrite, and allocate a separate frame buffer when it is not feasible. The LDC does not care if the input and output image pointers coincide, nor does it check any dependency violations.

The starting address of the input frame, corresponding to input coordinate (0, 0), is specified in the LDC_RD_BASE[31:0] RBASE bit field and offset in the LDC_RD_OFST[15:0] ROFST bit field ((Y and Cb/Cr base required for YCbCr4:2:0: LDC_420C_RD_BASE[31:0] RBASE)). The LDC does not clips input block to input frame size if any of the input block falls outside the input frame.

Note

- Any number of input blocks CAN fall partially or totally outside the input frame by assuming coordinates that are outside valid range (negative or exceeding maximum image width defined by the line offset).
- If any output pixel refers to any input pixel outside the input frame, the computed value for that output pixel would be same as neighbor pixel which falls into valid input frame. The other output pixels can still have correct outcomes.

7.7.4.2.11 LDC Input/Output Data Formats

Table 7-114 captures valid number of LDC input and output data mode/format combinations.

Copyright © 2026 Texas Instruments Incorporated

Table 7-114. LDC Supported Data Format Combinations

Input		Output	
Data Mode	Data format	Data Mode	Data format
420 420_Y 420_UV	8-bit	Same as input	8bit
			12-bit - packed
	12-bit - packed		12-bit - packed
	12-bit - unpacked		12-bit - unpacked
			8-bit (on channel[2/3] using LUT)
	12-bit - packed		8-bit (on channel[0/1] with shift) 8-bit (on channel[2/3] using LUT)
422	8-bit	420	8-bit
			12-bit – packed
		422	8-bit

Output data mode will be same as input data mode except when input data is 422, output data can also be converted to 420. In the case of input data format is 8-bit and output data format is 12-bit packed, valid data range is only 8-bit. Output data formatted into 12-bit packed format with 4 MSB bits being all zeros.

The following list contains the register fields used to configure data modes and formats:

- Input data mode - LDC_CORE_CTRL[4-3] IP_DATAMODE
- Input data format - LDC_CORE_CTRL[6-5] IP_DFMT
- Output Luma data format – LDC_CORE_LSE_BUF_CFG_j (j = 0, 2) PIX_FMT_PW
- Output Chroma data format – LDC_CORE_LSE_BUF_CFG_j (j = 1, 3) PIX_FMT_PW

LDC supports YCbCr 422 in the UYVY input data format. The sample grid for YCbCr 422_UYVY is shown in Figure 7-105.

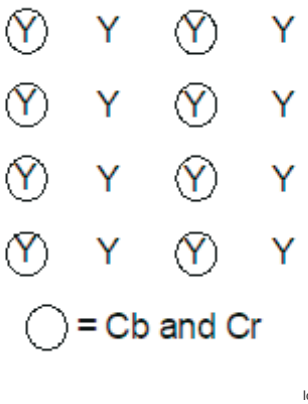

Figure 7-105. LDC Sample Grids for UYVY

UYVY data are stored in 8-bit per color components as shown in Table 7-115.

Table 7-115. LDC UYVY 8-bit Per Color Components

31			0
Y(1)	Cr(0)	Y(0)	Cb(0)

The sample grid for YUV420 NV12 is shown in Figure 7-106.

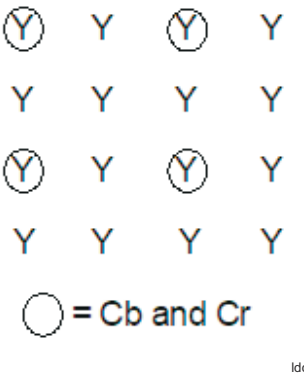

Figure 7-106. LDC Sample Grids for NV12

YCbCr 420 data are stored 8-bit per color components, and in two planes, Y by itself and Cb/Cr interleaved as shown in Table 7-116

Table 7-116. LDC YCbCr 420 data stored 8-bit per color components

31			0
(Y plane) Y(3)	Y(2)	Y(1)	Y(0)
(Cb/Cr plane) Cr(2)	Cb(2)	Cr(0)	Cb(0)

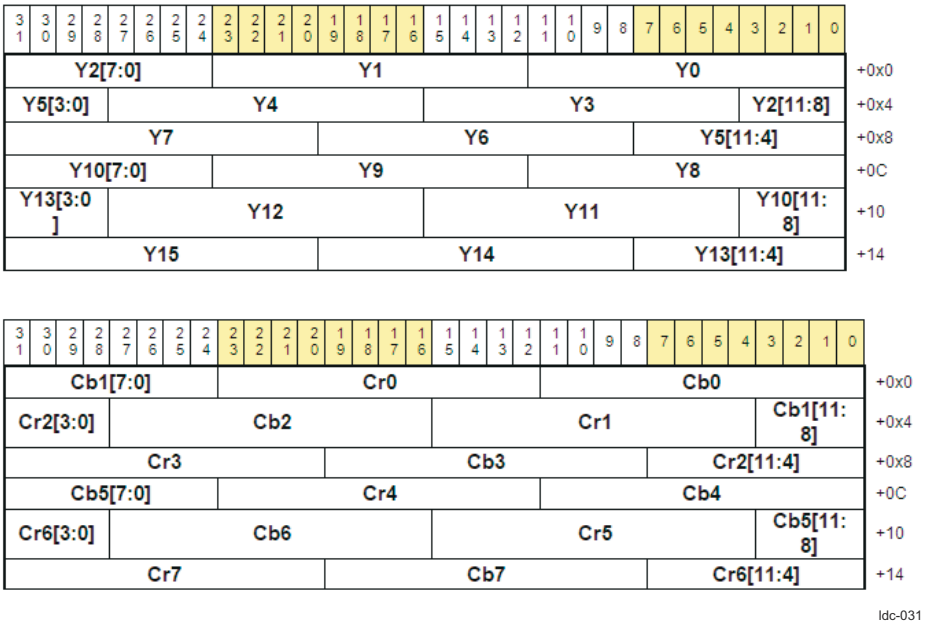

Figure 7-107. LDC YUV420 (2-plane 12-bit Fully Packed Format)

7.7.4.2.12 LDC YUV422 to YUV420 Conversion

Supporting input YUV422 format enables external sensors providing the YUV data directly. YUV422 to YUV420 conversion is done after pixel interpolation and achieved by dropping odd Chroma lines in the block. This retains the Chroma co-sited relation with Luma as at LDC input.

Copyright © 2026 Texas Instruments Incorporated

Figure 7-108. LDC YUV422 to YUV420 Conversion

7.7.4.2.13 LDC SL2 Interface (LSE)

LDC Output write interface is handled by LSE sub-module. LSE (Load Store Engine) module is a common component integrated in VPAC to perform data load and store tasks on the SL2 memory for the HWA algorithm core.

VBUSP interface is be used to transfer the data from LDC Core to LSE.

For more LSE details, see *Load Store Engine (LSE)*.

7.7.4.2.13.1 LDC PSA (Parallel Signature Analysis)

LSE integrates a CRC signature capture mechanism on each output channel data to verify the integrity of the HWA's internal paths. When enabled, every valid pixel data from the CORE is sampled by a CRC module to update the signature for the channel before the data is packed and sent to the SL2 buffer. Note that data used for PSA is raw data from the CORE rather than data written into SL2 with container alignment. For LDC, PSA signature is calculated in the same order as CORE data transfer to LSE which is 3D block order as against frame order. At the end of frame condition, the final signature is saved in a separate read-only signature register (VPAC_LDC_LSE_PSA_SIGNATURE_y y=0..#_of_Output Channel-1) till the next end of frame condition for software to read and compare it against the golden reference signature. The read-only register keeps the last saved value until a reset (set to 0) or is replaced by another frame data signature.

7.7.4.2.14 LDC LUT Mapped Dual Output

LDC produces parallel 8-bit and 12-bit outputs to support surround view and ADAS applications concurrently. LDC produces parallel 8-bit output from 12-bit input using LUT based implementation. This 8-bit output is written into SL2 using LSE output channels (channel[2] for Luma and channel[3] for Chroma). Though use case requires 8-bit output, hardware is designed to be generic which supports any 8-12bit to 8-12bit conversion.

12 or 8 bit generated by data interpolation block is mapped to 8 to 12 bits using a LUT based mapping. The LUT is similar to the LUTs used in VISS and is a linear LUT with 513 entries.

The LUTs are sized to provide 513 locations of data, to enable linear interpolation for all locations. The internal weights are sized as 3 bits since the maximum delta between 2 steps is only 4095/512 = 8. The logic is designed to scale for bit width and can support anything from 8 to 12 bits of input to support different use cases. However, since the step size is different depending on the input bit width, the bit selection and weight calculation logic is designed to account for that. LSE Shift operation can be instead of LUT to reduce bit width from 12 down to 8.

The input bit width (IN_BITDEPTH explained above) is specified using a dedicated register. Output is clipped to programmable clip value ($2^{BitClip\ -1}$). Combination of IN_BITDEPTH, LUT values and Clip value programation allows any 8-12bit to 8-12bit conversion.

7.7.4.2.15 LDC Band Width Controller

A Bandwidth Limiter is required to limit the mean BW that LDC can request over the VBUSM Read interface. The software sets the maximum allowed bytes per cycle in the register, LDC_CORE_VBUSMR_CFG[27-16] BW_CTRL.

To determine the maximum allowed bytes per cycle, the software needs to know the configuration of LDC, which determines the maximum input block size. Given a specific configuration, the ldc_findMaxInputBuffer utility provided with the functional C model, can be used to give the maximum input block size. The performance requirements determine the maximum number of cycles allowed per block.

7.7.4.2.16 LDC Input Block Fetch Limit

In order to limit the band width hogging by LDC in case of wrong mesh table data, maximum amount of input block pixel data being fetched will be capped at maximum internal memory available for respective data (Note: Luma and Chroma has different size internal buffers).

In YUV420* modes, limit is imposed by Luma data. Pixel data fetch is stopped on detecting the overflow condition and interrupt event is generated. Maximum of 2 requests can be issued upon overflow detection. In case of mesh data, only interrupt event is generated on detecting overflow condition and there is no stalling of fetch. These events are generated for the first overflow case per frame.

7.7.4.2.17 LDC HTS Interface

The HTS interface is used to synchronize between blocks in VPAC Subsystem. In the case of LDC, it controls the start of LDC operation by issuing hts_init. LDC will be waiting for hts_init once it is enabled, so LDC is expected to be enabled before issuing hts_init.

HTS also controls the LDC output write which will indirectly control all LDC operations (that is, fetch and processing). LDC will start writing output pixel data when only it receives hts_tstart for that particular block. Once all output data is written, LDC will generate hts_tdone (also hts_eop if it is last block of the frame).

7.7.4.2.18 LDC VBUSM Read Interface

VBUSM Read interface has following features

- Data Width – 128 Bit
- Address width – 48 Bit
- Maximum of number of Tags – 32
  - Design can be constrained to use lesser number of Tags
- Maximum Command Size: Programmable
  - 32/64/128/256 Bytes
  - Command will split at maximum command size address boundary
- Chanid Encode: chanid[1:0] identify the source/type of the data interface is requesting. Chanid[11:2] is tied low.
  - Chanid[1:0] decoding
    - 00 – Mesh Data.
    - 01 – Luma data in 420 mode/422 data.
    - 10 – Chroma data in 420 mode.

7.7.4.3 LDC Programmers Guide

7.7.4.3.1 LDC Programming Geometric Distortion Mode

Geometric distortions, barrel and pincushion distortion, can be corrected on UYVY and NV12 data formats. The Mesh based back mapping is used in this mode. An additional affine transform can be configured at the same time.

1. Check and wait for LDC_CORE_CTRL[2] BUSY to become IDLE (0).
2. Set LDC_CORE_CTRL[4-3] IP_DATAMODE for UYVY (0) or NV12 data (2). Program LDC_CORE_CTRL[6-5] IP_DFMT to required data storage format.
3. Set LDC_CORE_CTRL[1] LDMAPEN = 1 to enable lens distortion back mapping.

Copyright © 2026 Texas Instruments Incorporated

4. Set the input frame base address in LDC_CORE_RD_BASE_H / LDC_CORE_RD_BASE_L registers. Note that the frame base address must be aligned on a 16-byte boundary. In case of YUV420, YUV422SP, Y1_Y2 and Y1_Y2Y3 modes, configure LDC_CORE_RD_420C_BASE_H / LDC_CORE_RD_420C_BASE_L registers for Chroma Data.
5. Set the input frame line offset in LDC_CORE_RD_OFST[15-0] OFST.
6. If reading the input image from a circular buffer:
   a. Set LDC_CORE_CTRL[9] IP_CIRCEN = 1.
   b. LDC computes the row number and applies modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in LDC_CORE_RD_OFST[29-16] MOD register field. In YUV420 modes, the number of rows in the buffer is MOD/2. In others modes, the number of rows in the buffer is MOD for both Y buffer and Cb/Cr buffer.
7. Set the tile size in VPAC_LDC_REGION_OUT_BLKSZ_j[15-8] OBH and VPAC_LDC_REGION_OUT_BLKSZ_j[7:0] OBW. Note the constraints on OBW in Table 7-113.
8. Set the pixel pad in VPAC_LDC_REGION_OUT_BLKSZ_j[19-16] PIXPAD.
9. Set the input frame size in LDC_CORE_INPUT_FRSZ[29-16] H and LDC_CORE_INPUT_FRSZ[13-0] W.
10. Set the output frame size in LDC_CORE_MESH_FRSZ[29-16] H and LDC_CORE_MESH_FRSZ[13:0] W. Mesh data has to be present for entire frame after transform.
11. Set the output compute frame size in LDC_CORE_COMPUTE_FRSZ[29-16] H and LDC_CORE_COMPUTE_FRSZ[13-0] W.
12. Set the starting output point in LDC_CORE_INITXY[12-0] INITX and LDC_CORE_INITXY[28-16] INITY.
13. Configure SL2 Interface programming registers. Details of LSE configuration is captured in Section 7.7.4.3.4.
14. Set the mesh offset table pointer to the correct address (LDC_CORE_MESH_BASE_H / LDC_CORE_MESH_BASE_I[31-0] ADDR and LDC_CORE_MESH_OFST[15-0] OFST). Set the table down sampling factor for MxM down sampling in LDC_CORE_MESHTABLE_CFG[2-0] M.
15. Set the Y plane interpolation type to bilinear or bi-cubic in LDC_CORE_CFG[6] YINT_TYP.
16. If also using affine transform, set the six affine transform parameters in LDC_CORE_AFF_AB.A, LDC_CORE_AFF_AB.B, LDC_CORE_AFF_CD.C, LDC_CORE_AFF_CD.D, LDC_CORE_AFF_EF.E, and LDC_CORE_AFF_EF.F. If affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, and F = 0.
17. If also using perspective transform, enable LDC_CORE_CTRL[7] PWARPEN and set LDC_CORE_PWARP_GH[15-0] G and LDC_CORE_PWARP_GH[31-16] H. If perspective transform is not used, disable LDC_CORE_CTRL[7] PWARPEN and set LDC_CORE_PWARP_GH[15-0] G = 0 and LDC_CORE_PWARP_GH[31-16] H = 0.
18. Set LDC_CORE_CTRL[0] LDC_EN = 1 to start the LDC operation.
19. Start the HTS init sequencing. LDC fetch/processing is gated with hts_init.
20. Wait for LDC_CORE_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

7.7.4.3.2 LDC Programming Rotational Video Stabilization (Affine Transformation)

In the rotational video stabilization use case, consecutive frames capturing the same scene are aligned to minimize camera shake. Camera motions cause the frames to have translation or rotation differences. Thus, the frames need to be aligned to maintain a stable output video. The affine transform offers control to account for scaling, rotation, and translation transforms. For example, the rotation use case can be parameterized with the following affine transform parameters:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} a & b \\ d & e \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} c \\ f \end{bmatrix}$$

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} h_o - h_o \cos(\theta) - v_o \sin(\theta) \\ v_o - v_o \cos(\theta) - h_o \sin(\theta) \end{bmatrix}$$

ldc-035

Copyright © 2026 Texas Instruments Incorporated

where theta is the angle of rotation. In the scaling case, the affine transform uses:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} \alpha & 0 \\ 0 & \alpha \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} h_o(1-\alpha) \\ v_o(1-\alpha) \end{bmatrix}$$

ldc-036

where alpha is the scale factor. Translation uses an identity matrix along with the translation vector as the affine transform parameters, as in:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} T_h \\ T_v \end{bmatrix}$$

ldc-037

where Th and Tv are the translation parameters. More complex transforms can be derived and the affine transformation is general so that optimization routines may be used to provide the best parameters to align two frames. In all affine transforms, the perspective warp parameters, g and h, should be set to 0.

The following steps need to be performed by the application to initialize and run LDC to perform affine transform.

1. Check and wait for LDC_CORE_CTRL[2] BUSY to become IDLE (0).
2. Set LDC_CORE_CTRL[4-3] IP_DATAMODE and LDC_CORE_CTRL[6-5] IP_DFMT to required data mode and format.
3. If lens distortion correction is performed at the same time as the affine transform, set LDC_CORE_CTRL[1] LDMAPEN = 1. Otherwise, set LDC_CORE_CTRL[1] LDMAPEN = 0.
4. Set the input frame base address in LDC_CORE_RD_BASE_H / LDC_CORE_RD_BASE_I. Note that the frame base address must be aligned on a 16-byte boundary.
5. Set the input frame line offset in LDC_CORE_RD_OFST[15-0] OFST.
6. If reading the input image from a circular buffer:
   a. Set LDC_CORE_CTRL[9] IP_CIRCEN = 1.
   b. If using row address, LDC computes the row number and applies a modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in LDC_CORE_RD_OFST[29-16] MOD. In YUV420 modes, the number of rows in the Y buffer is MOD and the number of rows in the Cb/Cr buffers is MOD/2. In others modes, the number of rows in the buffer is MOD for both Y buffer and Cb/Cr buffer.
7. Set the tile size in LDC_CORE_OUT_BLKSZ[15-8] OBH and LDC_CORE_OUT_BLKSZ[7-0] OBW. Note the constraints on OBW in Table 7-113.
8. Set the pixel pad in LDC_CORE_OUT_BLKSZ[19-16] PIXPAD.
9. Set the input frame size in LDC_CORE_INPUT_FRSZ[29-16] H and LDC_CORE_INPUT_FRSZ[13-0] W.
10. Set the output frame size in LDC_CORE_MESH_FRSZ[29-16] H and LDC_CORE_MESH_FRSZ[13-0] W. Mesh data has to be present for entire frame after transform.
11. Set the output compute frame size in LDC_CORE_COMPUTE_FRSZ[29-16] H and LDC_CORE_COMPUTE_FRSZ[13-0] W.
12. Set the starting output point in LDC_CORE_INITXY[12-0] INITX and LDC_CORE_INITXY[28-16] INITY.
13. Configure SL2 Interface programming registers. Details of LSE configuration is captured in Section 7.7.4.3.4.
14. If the data format is NV12, set the 420 UV input plane base address in LDC_CORE_RD_420C_BASE_H / LDC_CORE_RD_420C_BASE_I. This address must be 16-byte aligned.
15. Set the mesh offset table pointer to the correct address (LDC_CORE_MESH_BASE_H / LDC_CORE_MESH_BASE_I and LDC_CORE_MESH_OFST. Set the table down sampling factor for MxM down sampling in MESHTABLE_CFG.M.
16. Set the Y plane interpolation type to bilinear or bicubic in LDC_CORE_CFG[6] YINT_TYP.

Copyright © 2026 Texas Instruments Incorporated

17. Set the six affine transform parameters in LDC_CORE_AFF_AB.A, LDC_CORE_AFF_AB.B, LDC_CORE_AFF_CD.C, LDC_CORE_AFF_CD.D, LDC_CORE_AFF_EF.E, and LDC_CORE_AFF_EF.F. If affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, and F = 0.
18. Disable perspective warp transform with LDC_CORE_CTRL[7] PWARPEN = 0. Set the two perspective transform parameters LDC_CORE_PWARP_GH[15-0] G = 0 and LDC_CORE_PWARP_GH[31-16] H = 0.
19. Set LDC_CORE_CTRL[0] LDC_EN = 1 to start the LDC operation.
20. Start the HTS init sequencing. LDC fetch/processing is gated with hts_init.
21. Wait for LDC_CORE_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

7.7.4.3.3 LDC Programming Perspective Transformation

Perspective transforms are used to align the image data of two different cameras viewing the same scene from different positions. It can also be used in the case of stereo image rectification to align the epipolar lines of the left/right image pair with their scan lines.

The following steps need to be performed by the application to initialize and run LDC to perform perspective transform.

1. Check and wait for LDC_CORE_CTRL[2] BUSY to become IDLE (0).
2. Set LDC_CORE_CTRL[4-3] IP_DATAMODE and LDC_CORE_CTRL[6-5] IP_DFMT to required data mode and format.
3. If lens distortion correction is performed at the same time as the perspective transform, set LDC_CORE_CTRL[1] LDMAPEN = 1. Otherwise, set LDMAPEN = 0.
4. Set the input frame base address in LDC_CORE_RD_BASE_H / LDC_CORE_RD_BASE_I. Note that the frame base address must be aligned on a 16-byte boundary.
5. Set the input frame line offset in LDC_CORE_RD_OFST[15-0] OFST.
6. Set the tile size in LDC_CORE_OUT_BLKSZ[15-8] OBH and LDC_CORE_OUT_BLKSZ[7-0] OBW. Note the constraints on OBW in Table 7-113.
7. Set the pixel pad in LDC_CORE_OUT_BLKSZ[19-16] PIXPAD.
8. Set the input frame size in LDC_CORE_INPUT_FRSZ[29-16] H and LDC_CORE_INPUT_FRSZ[13-0] W.
9. Set the output frame size in LDC_CORE_MESH_FRSZ[29-16] H and LDC_CORE_MESH_FRSZ[13-0] W. Mesh data has to be present for entire frame after transform.
10. Set the output compute frame size in LDC_CORE_COMPUTE_FRSZ[29-16] H and LDC_CORE_COMPUTE_FRSZ[13-0] W.
11. Set the starting output point in LDC_CORE_INITXY[12-0] INITX and LDC_CORE_INITXY[28-16] INITY.
12. Configure SL2 Interface programming registers. Details of LSE configuration is captured in Section 7.7.4.3.4.
13. If the data format is NV12, set the 420 UV input plane base address in LDC_CORE_RD_420C_BASE_H / LDC_CORE_RD_420C_BASE_I. This address must be 16-byte aligned.
14. Set the mesh offset table pointer to the correct address (LDC_CORE_MESH_BASE_H / LDC_CORE_MESH_BASE_I and LDC_CORE_MESH_OFST. Set the table down sampling factor for MxM down sampling in MESHTABLE_CFG.M.
15. Set the Y plane interpolation type to bilinear or bicubic in LDC_CORE_CFG[6] YINT_TYP.
16. Set the eight perspective transform parameters in LDC_CORE_AFF_AB.A, LDC_CORE_AFF_AB.B, LDC_CORE_AFF_CD.C, LDC_CORE_AFF_CD.D, LDC_CORE_AFF_EF.E, and LDC_CORE_AFF_EF.F. If affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, F = 0,G = 0 and H = 0. Enable LDC_CORE_CTRL[7] PWARPEN = 1.
17. Set LDC_CORE_CTRL[0] LDC_EN = 1 to start the LDC operation.
18. Start the HTS init sequencing. LDC fetch/processing is gated with hts_init.
19. Wait for LDC_CORE_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

7.7.4.3.4 LDC Programming LSE

Following provides the LSE general programming guideline.

It also captures an additional secondary specific use case configuration values for some registers.

- Frame Size = 1920x1080

Copyright © 2026 Texas Instruments Incorporated

- Output Block size = 64x32
- Luma data being consumed by MSC and Chroma is written out by UDMA
  - Block to line conversion done for Luma data via SL2.
  - Chroma data is written out at block level.
- Circular buffer size just to do ping-pong between LDC – MSC(Y) and LDC – UDMA(C)
- 12-bit pixel data

1. Pixel Data Format
   a. LDC_CORE_LSE_BUF_CFG_j (PIX_FMT_PW, PIX_FMT_CNTRSZ, and PIX_FMT_ALIGN) parameters define the pixel output data format for this output channel.
   b. Common data formats:
      i. Fully packed 12-bit : PIX_FMT_PW=1, PIX_FMT_CNTRSZ=1, PIX_FMT_ALIGN=0
      ii. 12-bit unpacked (MSB aligned) : PIX_FMT_PW = 1, PIX_FMT_CNTRSZ=2, PIX_FMT_ALIGN=1

2. Output SL2 Circular Buffer Configuration
   a. LDC_CORE_LSE_BUF_ATTR0_j (buf_stride) – define the line stride size (must be 64 byte multiple)
      i. LDC_CORE_LSE_BUF_ATTR0_j[15-6] BUF_STRIDE = 2880 (1920 * 1.5)
      ii. LDC_CORE_LSE_BUF_ATTR0_j[15-6] BUF_STRIDE = 96 (64 * 1.5)
   b. LDC_CORE_LSE_BUF_ATTR0_j (cbuf_size) – define the size of the circular buffer in the SL2 (number of lines)
      i. LDC_CORE_LSE_BUF_ATTR0_j[24-16] CBUF_SIZE = 68 (2*OBH+4)
      ii. LDC_CORE_LSE_BUF_ATTR0_j[24-16] CBUF_SIZE = 64 (2*OBH)

3. Output SL2 Circular Buffer 2D mode Configuration (applicable for LDC only - TBD)
   a. LDC_CORE_LSE_BUF_ATTR1_j (buf_blk_width) – defines the number of bytes equivalent to OBW (output block width) pixels.
      i. LDC_CORE_LSE_BUF_ATTR1_j.buf_blk_width = 96 (64*1.5)
   b. LDC_CORE_LSE_BUF_ATTR1_j (cbuf_bpr) – defines the number of 2D blocks per row in the SL2 circular buffer.
      i. LDC_CORE_LSE_BUF_ATTR1_j[25-16] CBUF_BPR_CHAN = 30
      ii. LDC_CORE_LSE_BUF_ATTR1_j[25-16] CBUF_BPR_CHAN = 1

4. Base Address and Channel Enable:
   a. LDC_CORE_LSE_BUF_BA_j[23-6] ADDR – defines the SL2 base address of the Circular buffer for this output channel.
   b. LDC_CORE_LSE_BUF_BA_j[31] ENABLE – enables this output channel.

7.7.4.3.5 LDC Programming Restrictions and Special Cases

The following list of LDC programming restrictions should be considered:

1. LDC_CORE_LSE_BUF_ATTR1_j[25-16] CBUF_BPR_CHAN supports 1023 number of block per row. Hence, with output block width of 8, maximum line size supported in SL2 memory is 8184 pixels.
2. In 422 mode, always program as data format as 8-bit (design does not select data format automatically based on mode)
3. Due to hardware limitations, make sure that input block size (height and width) does not cross 1023 (pixels/lines).
   - The hardware generates either PIX_IBLK_MEMOVF or MESH_IBLK_MEMOVF events in this case.
4. LDC_CORE_CTRL[0] LDC_EN should be high before issuing hts_init.

Copyright © 2026 Texas Instruments Incorporated

7.7.5 VPAC Multi-Scaler (MSC)

7.7.5.1 MSC Overview

VPAC_MSC (VPAC Multi-Scaler, hereinafter simply referred to also as MSC) is a Hardware Acceleration (HWA) module in Vision Pre-processing Accelator (VPAC) . MSC supports two sets of multi-output scaling filters to accelerate generation of pyramid (Octave) and intra-octave scales required by Optical Flow processing and DSP vision algorithms.

7.7.5.1.1 MSC Features

- 10 scaled outputs independently mapped to 1 or 2 processing threads (any number up to 10 scaler outputs can be mapped to one thread, while the remaining scaler outputs can be mapped to the other thread)
- Programmable scaling engine:
  - Pyramid or intra-octave scale generation
  - 1x ~ x/4 image downscaling
  - 1x generic separable convolution filtering
  - On-the-fly (OTF) or memory-to-memory (M2M) operation with line buffers in SL2 (thus, frame width not constrained by internal line buffer width).
- Polyphase filters:
  - 5-tap separable filter kernel structure
  - Programmable kernel sizes for vertical/horizontal filter (3, 4, or 5)
  - Polyphase implementation with support of 64 or 32 phases
  - Independent programming of vertical/horizontal filters with initial phase programming option
- Filter Coefficients (shared by all scalers):
  - Coefficients in signed 10-bit number (typically 1-bit integer with 8 fractional bits)
  - Programmable Coefficient shift size to set precision of coefficient number (shift size represents the fractional bit width)
  - 2 dedicated sets of 5-tap single phase filter coefficients (for example, Gaussian) for Pyramid (Octave) generation or custom convolution filtering.
  - 4 sets of 5-tap x 32 phase coefficients
    - Two can be combined to support 5-tap x 64-phase filters
    - First can be configured to hold additional 5-tap single-phase convolution filters for non-resizing application.
- Input/output format support:
  - Each thread can support the following input source formats:
    - One plane (uniform or interleaved format - Y, CbCr interleaved, R)
  - Each Input channel supports 8/12-bit pixel data in 8/12/16-bit pixel container with programmable LSB/MSB alignment
  - Each Output channel supports 8/12-bit pixel data in 8/12/16-bit pixel container with programmable LSB/MSB alignment
- Performance:
  - 1 cycle/pixel per plane
  - Input line skip for thread performing only pyramid-generation (50% less processing time)
- Other features:
  - Programmable Input and Output Regio of Interest (ROI) (or clipping) for each scaler
  - Support for Vertical and Horizontal edge Padding (replication) for both luma/chroma data plane inputs
- Functional Safety Support: CRC frame data signature capture on all output channels for fault detection in the data path.

7.7.5.1.2 MSC Not Supported Features

- More than 2 input threads or 10 outputs
- Block based operation for scalar
- Multi-component (RGB) Scaling
- Error checks for out of bound parameters

Copyright © 2026 Texas Instruments Incorporated

7.7.5.2 MSC Functional Description

7.7.5.2.1 MSC Functional Overview

VPAC_MSC consists of 10 programmable resizers performing multi-thread/multi-scaling operations (1-input to N-outputs and 1-input to M-outputs where N+M is 10 or less). Each processing thread of MSC HWA reads its input plane data from a Shared Memory buffers (SL2) circular line buffers, performs multi-scaling operations (ratios between X and 0.25X) on the selected thread channel input, and writes out results to SL2 circular line buffers. In case of OTF operation, the source data is generated from another HWA. In case of M2M operation, the source data is read from the DDR memory. Data transfers from/to SL2 to/from external memory (or another HWA) are handled by VPAC level DMA controller with transfer request events coming from VPAC top level HWA Thread Scheduler (HTS), see *HWA Threads Scheduler (HTS)*.

A typical configuration of the MSC module uses one input plane data to generate 7 intra-octave scales and the next octave image. Multi-pass processing is then utilized to generate up to next 6 or 7 sets of scales/octaves. Since the resolution after each octave is essentially reduced by 4x, the performance requirement for generating an infinite number of scales is bounded by 1.33x of the base input image pixel rate. The second input can be used to enable a pyramid generation processing for another input data or a set of scales/pyramid generation for chroma data as long as the total number of scales needed by both threads is 10 or less. Each resizer in a processing thread can access any coefficient set.

For details on MSC integration in VPAC, see Section 7.7.2,*VPAC Subsystem Level*.

7.7.5.2.1.1 MSC Submodule Details

The MSC_LSE (Load Store Engine) handles all interfacing to the SL2 memory space and performs following functions:

- Provides interface to SL2 circular buffers via a common VBUSM controller interface
- Manages input and output channel updates in sync with HTS
- Provides data unpacking for core and packing for SL2 interface
- Manages LSE specific configuration registers

The MSC_CORE performs all filtering operations for various 2-in/10-out multi-scaling/multi-thread configurations. It has no direct connection to external interface and it works on a frame data coming in and out in raster scan order.

The internal data transfers between the MSC_LSE and MSC_CORE are done over VBUSP write-only streaming interfaces.

7.7.5.2.1.1.1 MSC Load Store Engine (MSC_LSE)

7.7.5.2.1.1.1.1 MSC_LSE Overview

Figure 7-110 shows the MSC_LSC block diagram.

Copyright © 2026 Texas Instruments Incorporated

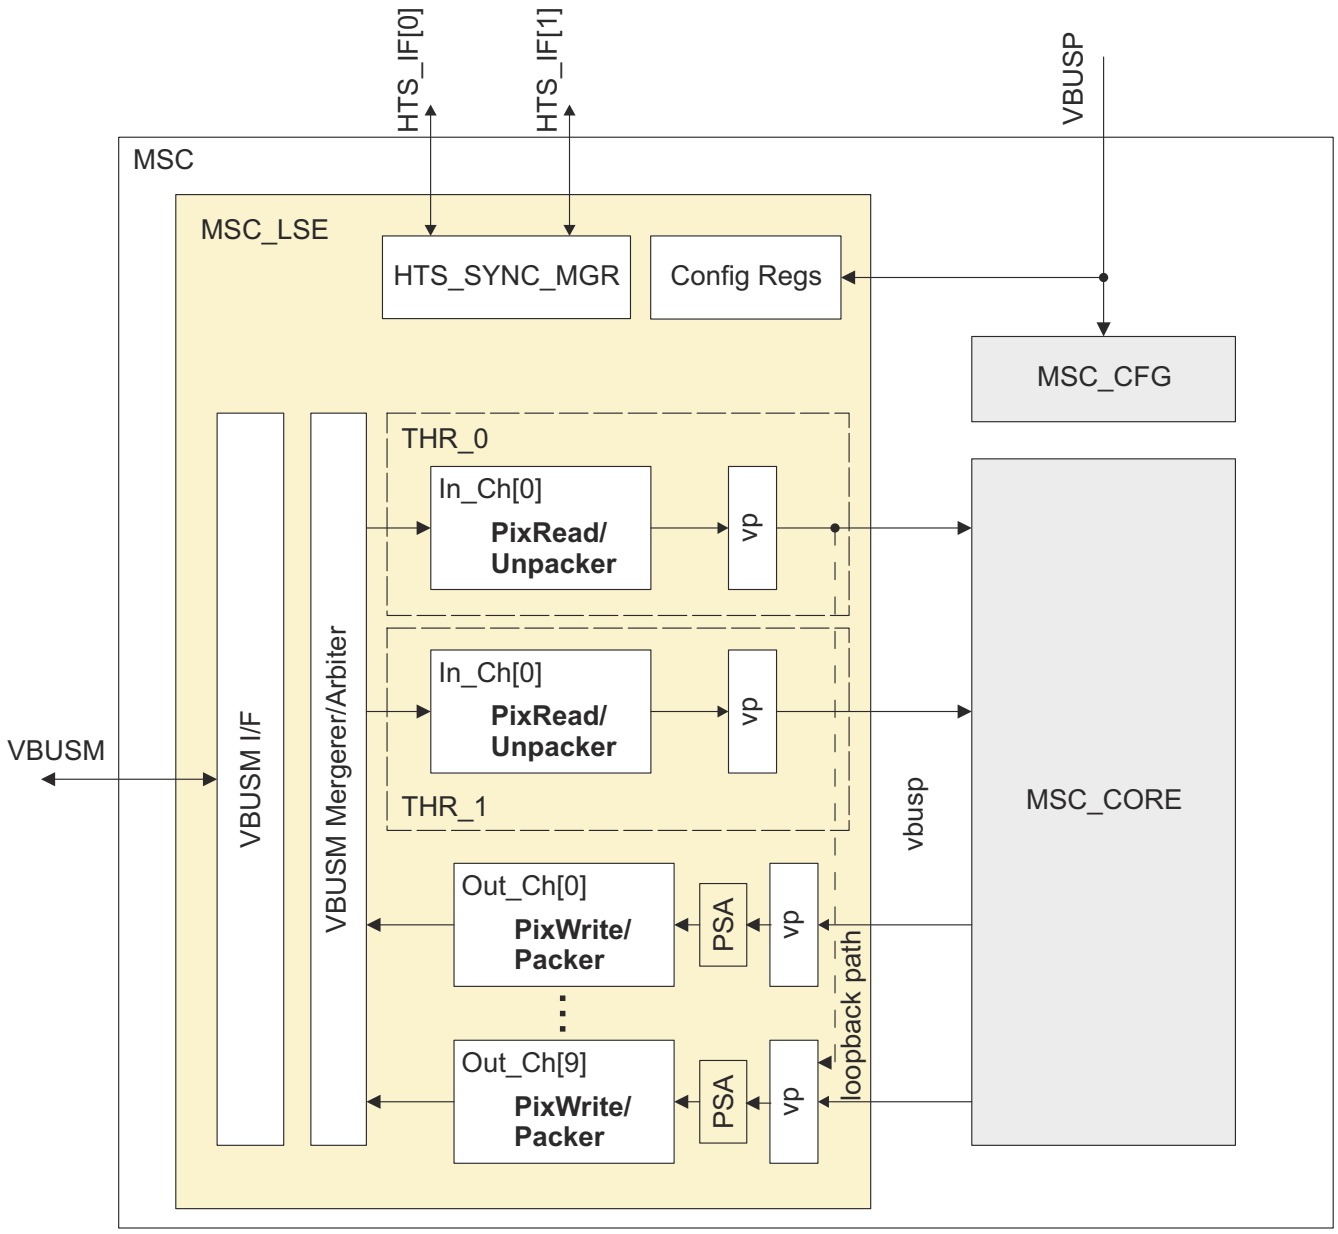

Figure 7-110. MSC_LSC Block Diagram

7.7.5.2.1.1.1.1.1 MSC_LSE Features

The MSC_LSE supports following VPAC_LSE features:

- Up to 2 processing threads supported (a thread is a processing chain with its own HTS start/done).
- Input channel features:
  - One SL2 input channel per thread with following features for the input channel:
    - Single data plane support
    - 8/12 packed and 12-bit unpacked source format support
    - Up to 5 lines - input kernel height support
    - 1D addressing mode only with CBUF address handling
    - Input Line Skip Support
    - Vertical boundary Edge Padding (Replication only) support
    - Channel enable
    - Video frame data with frame sync signals over a common vbusp streaming write-controller interface

Copyright © 2026 Texas Instruments Incorporated

- Output Channel Features:
  - Up to 10 SL2 output channels (pixel data output only)
  - Single data plane support for each output channel
  - Programmable thread mapping for each output channel
  - 8/12 packed and 12-bit unpacked output pixel data format support
  - 1D addressing mode support with CBUF address handling
  - Channel enable
  - Video frame data with frame sync signals (along with optional in-band control signals) over a separate vbusp streaming write-target interface
- HTS synchronization support
- LSE internal data bypass mode support
  - Input channel 0 can be configured to bypass/loopback mode the data to the core and/or directly to the output channel 9 (bypassing the core).

7.7.5.2.1.1.1.2 MSC_LSE Internal Data Loopback Channel

The MSC_LSE provides a data loopback channel.

When enabled (VPAC_MSC_LSE_CFG_LSE[0] LOOPBACK_EN), the LSE sends the “loopback-enabled” input channel unpacked data directly to the designated output channel packing logic without going through the HWA_CORE. The looped back data can be packed in a different format in the output channel to perform a data format conversion or can be packed in the same format as the input.

When the loopback mode is enabled, the “loopback” designated output channel is no longer available for HWA_CORE output data transfer. But, the input channel can still operate normally to read in the data for the HWA_CORE (provided that the other output channel is used for transferring out the HWA_CORE output data) by setting VPAC_MSC_LSE_CFG_LSE[1] LOOPBACK_CORE_EN. In this mode, the input channel flow is throttled by both the core and the loopback data path.

The data flow of the loopback mode is also controlled by the HTS synchronization signals.

7.7.5.2.1.1.1.3 MSC_LSE PSA Support

As a safety function, LSE integrates a CRC signature capture mechanism on each output channel data to verify the integrity of the HWA internal paths. When enabled (VPAC_MSC_LSE_CFG_LSE[8] PSA_EN), every valid transfer frame data from the MSC is passed through a CRC module to update the signature for the channel before the data is packed and sent to the SL2 buffer. At the end of frame condition, the final signature is saved in a separate read-only signature register (VPAC_MSC_LSE_PSA_SIGNATURE_y[31-0] VAUE = 0,...,Number_of_Output Channel-1) till the next end of frame condition for software to read and compare it against the golden reference signature.

The PSA signature register is based on the following IEEE 802.3 standard 32-bit CRC polynomial:

$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1$

The PSA module is inserted in the LSE data path as shown in Figure 7-110.

7.7.5.2.1.1.1.4 MSC_LSE Feature Detailed Description

For detailed LSE feature description, see *Load Store Engine (LSE)*.

7.7.5.2.1.1.2 MSC_CORE (HWA Core)

The MSC_CORE (HWA_CORE) is configured as two multi-scaling engines each of which can perform 1-to many (multi) scaling operations on an independent input source. The number of outputs (scaler filters) assigned to each multi-scaling engine is user-configurable.

7.7.5.2.1.1.2.1 MSC_CORE Overview

Figure 7-111 shows the architectural overview of the MSC_CORE. Each reconfigurable multi-scaling engine in the MSC_CORE receives its input frame data from its own dedicated VP (vbusp write only target) interface. VP_IN_0 port is used for the thread #0 (multi-scaling engine-0) and VP_IN_1 port is used for the thread

Copyright © 2026 Texas Instruments Incorporated

#1 (multi-scaling engine-1). The THREAD_MAP parameter of the MSC_LSE output channel configuration register (VPAC_MSC_LSE_DST_BUF_CFG_j[7] THREAD_MAP) controls which input port is connected to which scaling filter (filter_0 ~ filter_9).

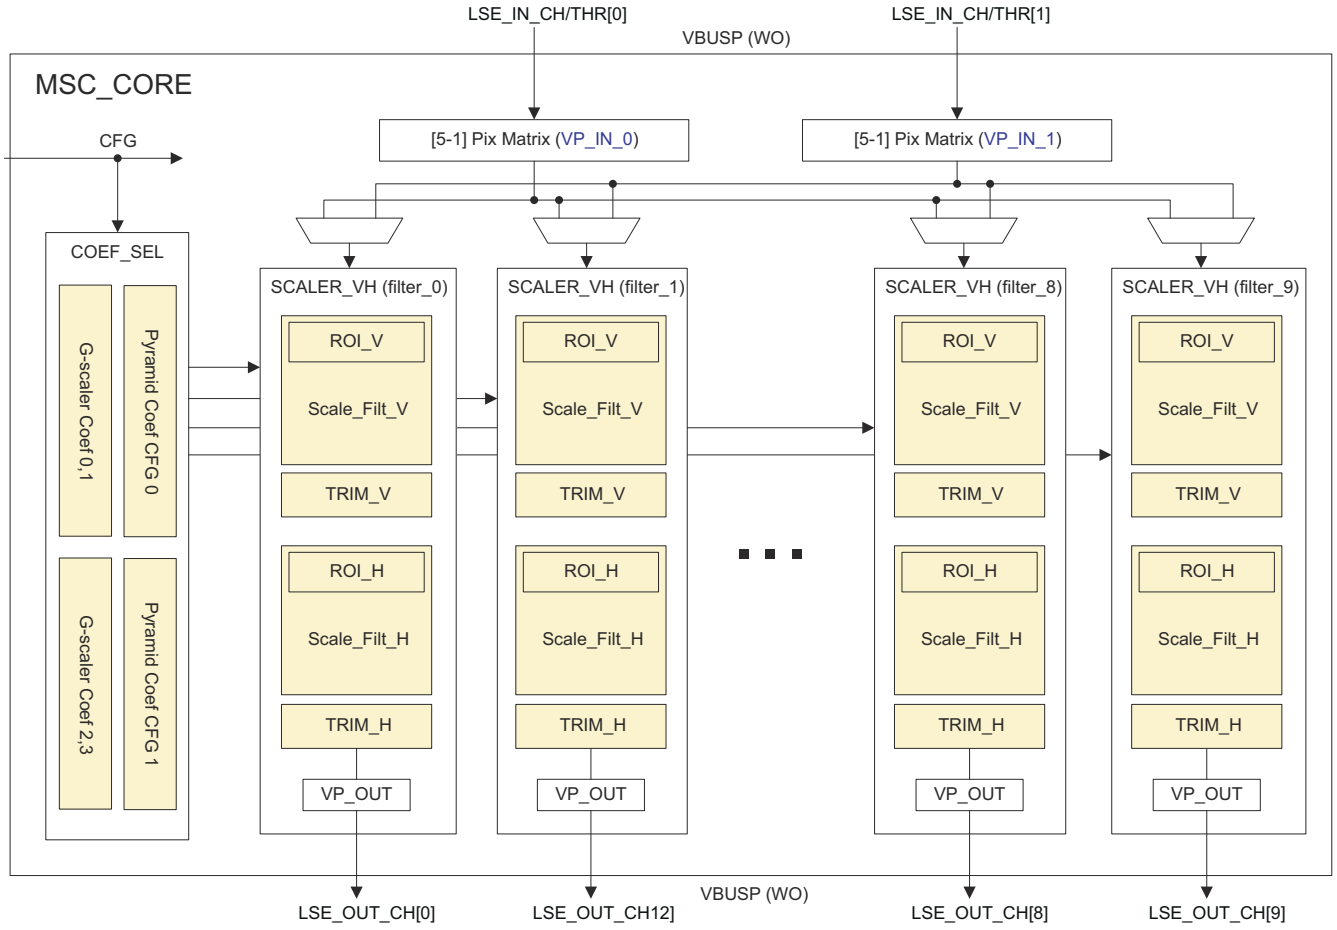

Figure 7-111. MSC_CORE Block Diagram

The scaling filter implements the vertical-before-horizontal architecture in order to avoid intermediate result line buffers that would be needed in the horizontal-before-vertical configuration. This architecture also allows the source frame width to be not restricted by internal line buffer sizes.

Each scaling filter in the MSC_CORE consists of 5-tap (32/64-phase) Polyphase filter based vertical and horizontal resizers. At the input of each resizer, a ROI checker determines the input start position (that is, marks the input data as valid). Output of each resizer is then trimmed to the configured output size of the scaling filter in each respective direction.

For MSC, the vertical input edge padding is performed in the MSC_LSE while the horizontal input boundary padding is done within the MSC_CORE before the horizontal resizer.

7.7.5.2.1.1.2.2 Polyphase Filter of Vertical/Horizontal Resizers

7.7.5.2.1.1.2.2.1 Filter Data Path Logic

Figure 7-112 shows the micro-architecture of the polyphase filter data path. The 5-tap filter structure can be programmed to perform a 5-tap Gaussian filter (for Octave generation) or a 4-tap bi-cubic downscaling filter (for scale generation). Or, it can be configured to perform a custom convolution filter without resizing. Filter coefficients for any unused taps should be set to 0. For example, in case of a 4-tap filtering, C2(Fi) filter coefficient should be set to 0. For 3-tap filtering, C-2(Fi) and C2(Fi) filter coefficients should be set to 0.

Copyright © 2026 Texas Instruments Incorporated

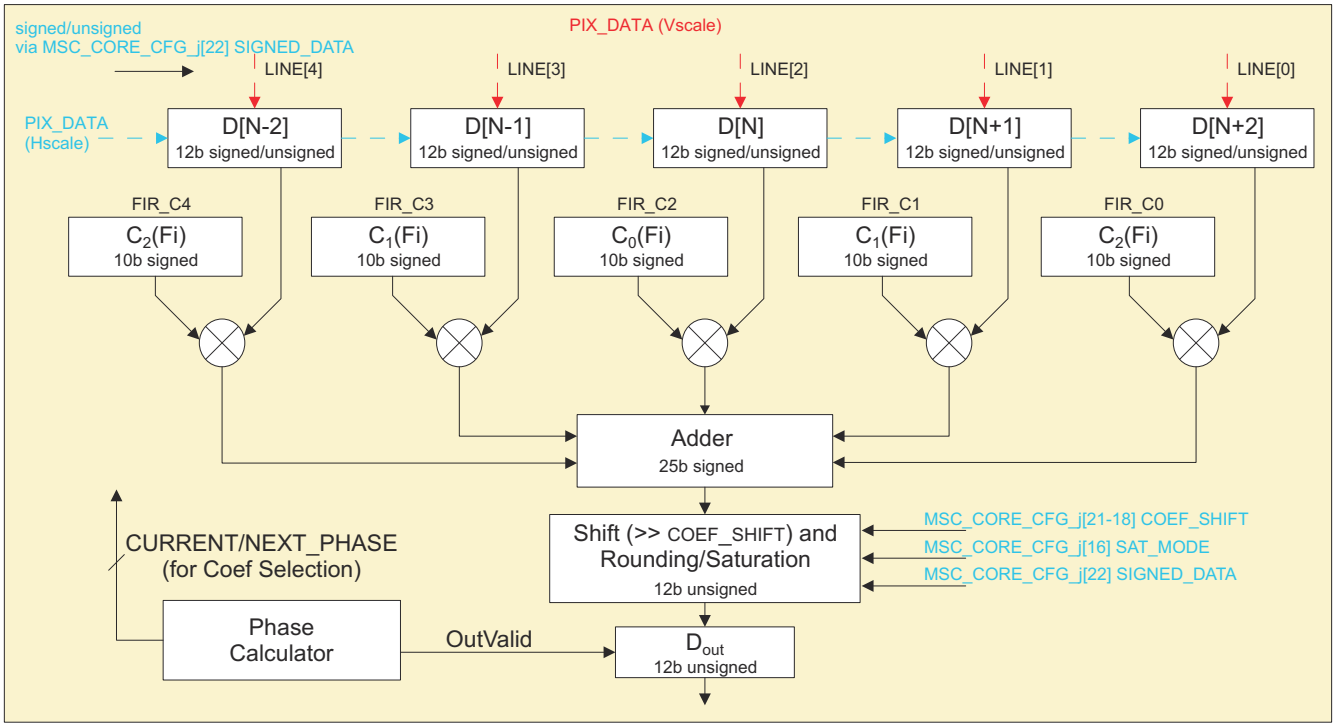

Figure 7-112. Polyphase Filter Micro-Architecture

Kernel Size Configuration

There is no separate configuration required to set the filter kernel size (number of taps) within the polyphase filter. The filter always works as a 5-tap filter but requires unused taps to be masked using the zero coefficients.

Coefficient Precision Selection

The precision of the coefficients is user-configurable using VPAC_MSC_CORE_CFG_j[21-18] COEF_SHIFT which determines the number of fractional bits of the coefficient.

Unsigned/Signed Data Type support

Typically for image resizing, the input and output data are in unsigned (positive) integer numbers in the range of [0..4095]. But, in some non-image convolution filtering (for example, Sobel filter), the input and output data may be in signed integer data format. The MSC supports a user-selectable data type mode bit (VPAC_MSC_CORE_CFG_j[22] SIGNED_DATA) per resizer to specify whether the input/output data is in signed or unsigned data format. The selection determines the input range and output clipping limits as shown below:

VPAC_MSC_CORE_CFG_0[22] SIGNED_DATA = 0 ->[0..4095]

VPAC_MSC_CORE_CFG_0[22] SIGNED_DATA = 1 -> [-2048..2047]

Note that all filters in the same processing thread should have the SIGNED_DATA bit set to a same value.

Rounding Logic

The rounding is done by “adding 0.5 and dropping fractional bits”. This achieves the following:

For data >= 0: “round to nearest, ties away from zero”

For data < 0: “round to nearest, ties toward zero”

Output Saturation Logic

For some non-image unsigned data filtering, the result of the final adder could be negative numbers. To avoid clipping all negative numbers to 0, the MSC filter data processing supports a mode

Copyright © 2026 Texas Instruments Incorporated

(VPAC_MSC_CORE_CFG_j[22] SAT_MODE = 1) to offset the result by 2048 and then clip the final result to [0..4095] in the output saturation logic to preserve the full data range.

Edge Pixel Replication

Pixel replication in vertical direction (edge line replication) is done in the MSC_LSE.

Pixel replication in horizontal direction (edge pixel replication) is performed in the horizontal filter. For chroma data plane, Cb/Cr pixel replication is done independently with edge Cb/Cr data respectively.

7.7.5.2.1.1.2.2.2 Filter Parameters

Table 7-117 lists the parameters used to define the configuration of the resizing (downsampling) vertical/ horizontal filters.

Table 7-117. Parameters of the Resizing (Downsampling) Vertical/Horizontal Filters

Parameter	Bit Precision	Description
FIRINC_V VPAC_MSC_CORE_FIRINC_j[30-16] VS	U15Q12 (Unsigned 15b number with 12-bit fraction)	Vertical Resizing Ratio value (vertical filter increment) Valid Range: 4096 (1x scaling) < FIRINC_V < 16384 (1/4x scaling) +1 in the above equation is optional. +1 forces non-repeating coefficients in integer ratio scaling cases.
FIRINC_H VPAC_MSC_CORE_FIRINC_j[14-0] HS	U15Q12 (Unsigned 15b number with 12-bit fraction)	Horizontal Resizing Ratio value (Horizontal filter increment)) Valid Range: 4096 (1x scaling) < FIRINC_V < 16384 (1/4x scaling)
ACC_INIT_V VPAC_MSC_CORE_ACC_INIT_j[27-16] VS	U12Q12 (Unsigned 12b number with 12b fraction)	Initial Vertical Resizer Phase Valid Range: 0 < ACC_INIT_V < 4095
ACC_INIT_H VPAC_MSC_CORE_ACC_INIT_j[11-0] HS	U12Q12 (Unsigned 12b number with 12b fraction)	Initial Horizontal Resizer Phase Valid Range: 0 < ACC_INIT_V < 4095

Additionally, Table 7-118 lists the mode parameters defined the filter operation and coefficient selection.

Table 7-118. Filter Mode and Coefficient Selection via VPAC_MSC_CORE_CFG_j Registers

Parameter	Bit Width	Description
SIGNED_DATA VPAC_MSC_CORE_CFG_j[22] SIGNED_DATA	1-bit	Integer type of input and output frame data: 0 : Unsigned 12-bit (default) 1 : Signed 12-bit
UV_MODE VPAC_MSC_CORE_CFG_j[17] UV_MODE	1-bit	Source data interleave format: 0 - non-interleaved (Y data) 1 - interleaved (UV data)
SP_VS_COEF_SEL VPAC_MSC_CORE_CFG_j[15-12] SP_VS_COEF_SEL	4-bits	Single Phase – Vertical Filter Coef Selection N : 5-tap/32-phase Filter Coef Set #0 (Entry N) where N=0-9 10 : Gaussian Filter #0 11 : Gaussian Filter #1 12-15 : Invalid When FilterMode=0 and N <10, then the multi-phase coef set #0 is dedicated for one or more single phase filters.

Copyright © 2026 Texas Instruments Incorporated

Table 7-118. Filter Mode and Coefficient Selection via VPAC_MSC_CORE_CFG_j Registers (continued)

Parameter	Bit Width	Description
SP_HS_COEF_SEL VPAC_MSC_CORE_CFG_j[10-7] SP_HS_COEF_SEL	4-bits	Single Phase – Horizontal Filter Coef Selection N : 5-tap/32-phase Filter Coef Set #0 (Entry N+10) where N=0-9 10 : Gaussian Filter #0 11 : Gaussian Filter #1 12-15 : Invalid When FilterMode=0 and N <10, then the multi-phase coef set #0 is dedicated for one or more single phase filters.
VS_COEF_SEL VPAC_MSC_CORE_CFG_j[5-4] VS_COEF_SEL	2-bits	Multi-phase Vertical Coef Selection 00 : 5-tap/32-phase Filter coef set #0 01 : 5-tap/32-phase Filter coef set #1 10 : 5-tap/32-phase Filter coef set #2 11 : 5-tap/32-phase Filter coef set #3
HS_COEF_SEL VPAC_MSC_CORE_CFG_j[3-2] HS_COEF_SEL	2-bits	Multi-phase Horizontal Coef Selection 00 : 5-tap/32-phase Filter coef set #0 01 : 5-tap/32-phase Filter coef set #1 10 : 5-tap/32-phase Filter coef set #2 11 : 5-tap/32-phase Filter coef set #3
PHASE_MODE VPAC_MSC_CORE_CFG_j[1] PHASE_MODE	1-bit	Filter Phase mode selection 0 - 64 phases 1 - 32 phases
FILTER_MODE VPAC_MSC_CORE_CFG_j[0] FILTER_MODE	1-bit	Filter Mode 0 – Single Phase Filter (for example, Gaussian Filter for Pyramid) 1 – Multi-phase Scaling Filter
FILT_SAT_MODE VPAC_MSC_CORE_CFG_j[16] SAT_MODE	1-bit	Filter Output Saturation Mode 0 - [0..4095] clipping 1 - [-2048.. 2047] clip followed by +2048 This parameter is used only when signed_data =0 (unsigned data type).
COEF_SHIFT VPAC_MSC_CORE_CFG_j[21-18] COEF_SHIFT	4-bits	Coef Shift Size: configures the precision of the 10-bit signed filter coefficients (valid Shift range: 5~9) : 5: Shift by 5 (5-bit fraction) 6: Shift by 6 (6-bit fraction) 7: Shift by 7 (7-bit fraction) 8: Shift by 8 (8-bit fraction) 9: Shift by 9 (9-bit fraction) Integer size = 9 - #_of_fraction_bits

7.7.5.2.1.1.2.2.3 Single-Phase Filter Parameters

For a single-phase filter configuration (VPAC_MSC_CORE_CFG_j[0] FILTER_MODE = 0), software must ensure that FIRINC parameters (VPAC_MSC_CORE_FIRINC_j[30-16] VS and VPAC_MSC_CORE_FIRINC_j[14-0] HS) are programmed with one of the following values only:

- 0x4000 (1/4 X resizing)
- 0x2000 (1/2 X resizing)
- 0x1000 (1X – no scaling)

Copyright © 2026 Texas Instruments Incorporated

VPAC_MSC_CORE_ACC_INIT_j[27-16] VS and VPAC_MSC_CORE_ACC_INIT_j[11-0] HS configuration values are ignored by the MSC hardware (internally set to 0x0) when VPAC_MSC_CORE_CFG_j[0] FILTER_MODE = 0. If any phase offsets are needed, the starting pixel/line locations of the frame and the filter coefficient values should be adjusted to implement the desired phase shift.

7.7.5.2.1.1.2.2.4 Interleaved Mode Handling

When the input is in the interleaved data format (for example, YUV420 Chroma data), the horizontal filter supports two sets of 5-input buffers (Cb and Cr buffers) and alternates filtering operation between two. Phase calculation and coefficient updates are done every other sample. Edge replications at the start of the line and at the end of the line are handled separately for Cb and Cr data.

There is no change in how the vertical filter handles an interleaved data format source.

7.7.5.2.1.1.2.2.5 Input Skip Line Support

When a processing thread is only performing an octave generation (1/2x single phase resizing), the next input lines can be offset by 2 lines since the output is only generated every other input line times. By skipping lines (VPAC_MSC_LSE_SRC_CFG_j[7] SRC_LN_INC_2), the SL2 access is reduced in half for this mode and the cycle time to complete an Octave generation is equal to ½ of the input frame size.

Line N: Read Line N-2, N-1, N, N+1, N+2

Line N+1: Skip

Line N+2: Read Line N, N+1, N+2, N+3, N+4

Line N+3: Skip

Even though “N+1” line processing is skipped, all source lines are still required for proper filtering. Therefore, the DMA transfer from DDR to SL2 should include all lines. VPAC_MSC_CORE_FIRINC_j[30-16] VS should be set to 4096 (1x resizing) to compensate for source line skip (if it is doing a ½ resizing).

Horizontal Skip is done normally as ½ x resizing by the core HScale Filter.

7.7.5.2.1.1.2.3 Scaler Filter Thread Mapping

The scaling filter_# (# = 0..9) is enabled and its input is connected to one of the processing thread source VP ports (VP_IN_0 or VP_IN_1) by configuring the output channel #n buffer configuration:

VPAC_MSC_LSE_DST_BUF_CFG_j[7] THREAD_MAP: 0 maps the filter to VP_IN_0, 1 maps to the VP_IN_1.

VPAC_MSC_LSE_DST_BUF_CFG_j[TBD] ENABLE: enables both filter and output channel

By mapping each output to a thread explicitly in the output channel configuration register, MSC guarantees that a filter can only be connected to one processing thread.

7.7.5.2.1.1.2.4 Filter Coefficients

Since each resizer needs to access the common coefficients independently, the coefficients are stored in registers (instead of memory). Each resizer selects directly from these register using the coefficient selection scheme as shown in Figure 7-113. The same mux is used to select either vertical or horizontal coefficients.

Copyright © 2026 Texas Instruments Incorporated

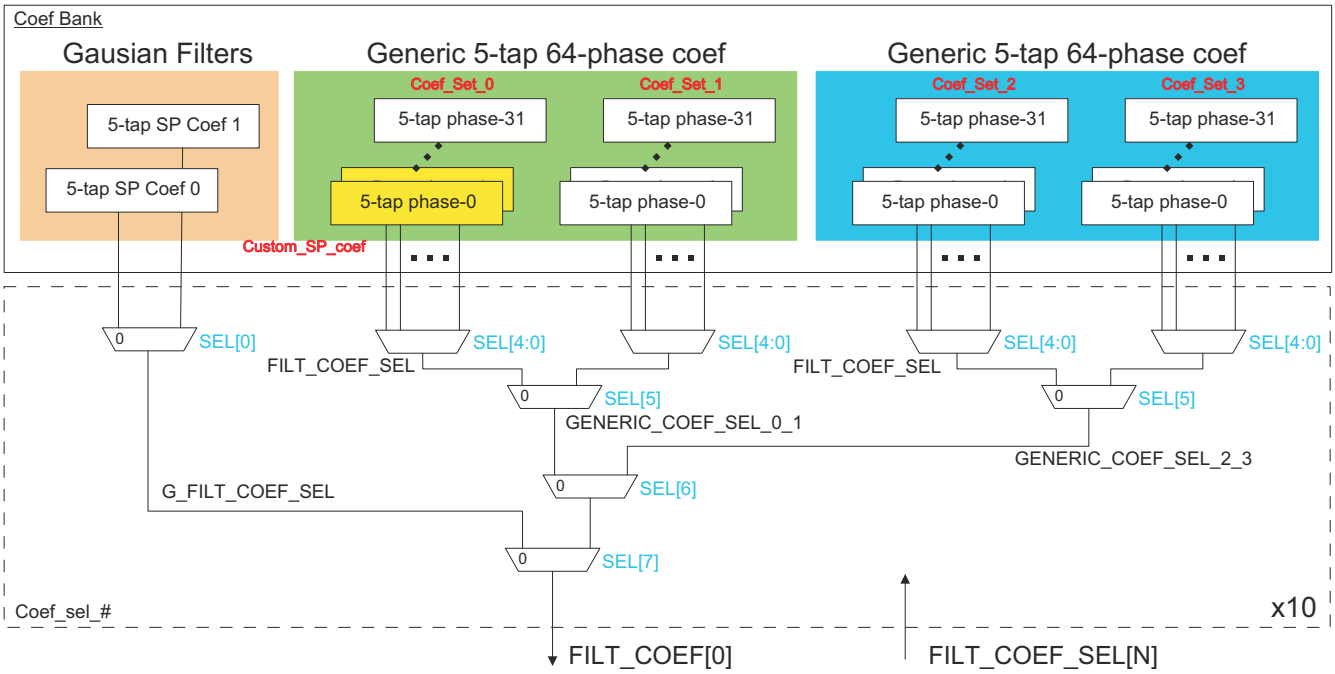

Figure 7-113. Coefficient Selection

7.7.5.2.1.1.2.4.1 Filter Coefficient Parameter Configuration

Each coefficient table entry consists of 5 coefficients stored in two memory mapped configuration registers - VPAC_MSC_CORE_C210_j and VPAC_MSC_CORE_C43_j. FIR_C4-0 parameters map to C-2, C-1, C0, C1, and C2 coefficients (see Figure 7-111).

7.7.5.2.1.1.2.4.2 3/4/5-Tap Filter Configuration

All filters operate in 5-tap filter mode – requiring 5-tap coefficients regardless of the filter usage. For less-than-5 tap filter configurations, coefficients corresponding to the unused taps should be set to 0.

For example, FIR_C0 and FIR_C4 will need to be set to 0x0 for a 3-tap configuration.

For 4-tap configuration, FIR_C0 will need to be set to 0x0.

7.7.5.2.1.1.2.5 Input/Output ROI Trimmers

Each scaler filter implements the ROI scaling as shown below with input and output trimmers. The input trimmer simply marks the beginning of the ROI to indicate where the valid source pixels and lines start in the source image. Doing the source ROI marker allows the exact specification of a sub-image in a common source image (no position or size restriction) while keeping the original boundary pixels (that is, not use the replicated pixels/ lines).

The output trimmers then uses destination size parameters (VPAC_MSC_CORE_OUT_SIZE_j[28-16] HEIGHT and VPAC_MSC_CORE_OUT_SIZE_j[12-0] WIDTH) to trim out the exact final output image sizes.

VPAC_MSC does not perform output size correction by stuffing extra pixels in the case the programmed VPAC_MSC_CORE_OUT_SIZE_j[28-16] HEIGHT and VPAC_MSC_CORE_OUT_SIZE_j[12-0] WIDTH exceeds the actual output size of the scaler. In this case, VPAC_MSC simply outputs the actual size.

7.7.5.2.2 Resizer Algorithm Details

This section describes the algorithm details of the Horizontal and Vertical Down-Scaling engines.

7.7.5.2.2.1 Multiple Scales Generations

For a high number of scales needed by vision image processing algorithm (for example, 32 or more), there are many options in generating the multiple scales as shown in Figure 7-114. Among the options, the “linear rescale

Copyright © 2026 Texas Instruments Incorporated

from octave resolution" gives the best tradeoff in video quality and design simplicity. The MSC implements 1-to-N multi-rescaling (that is, from one base image to multi-intra-scales and the next octave image generation) as shown as option B in Figure 7-114.

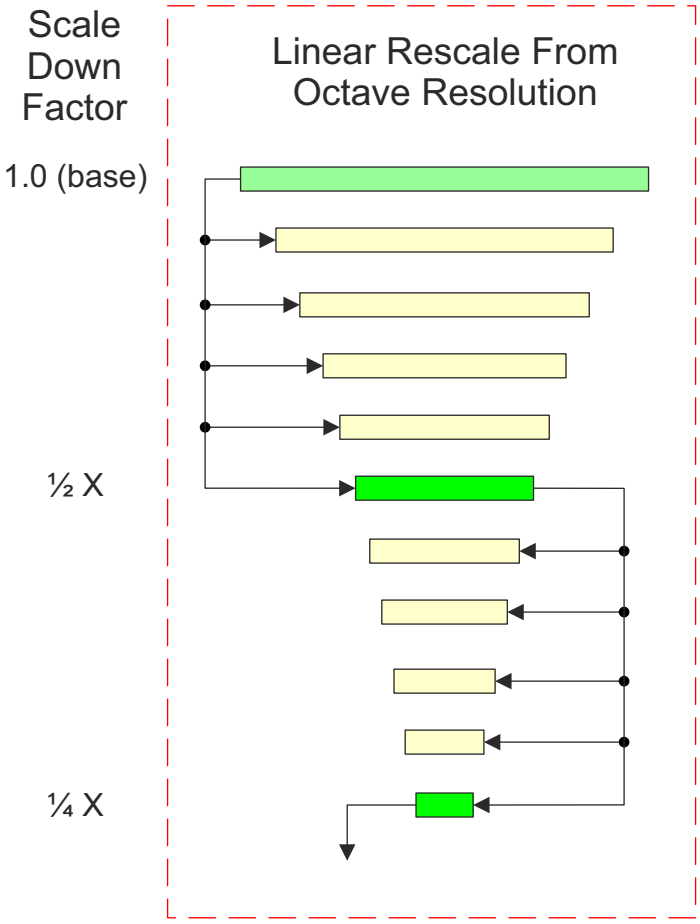

Figure 7-114. Multiple Scale Generation

7.7.5.2.2.2 Polyphase Filter

Both vertical and horizontal resizers in MSC hardware are implemented using a programmable Polyphase filter structure supporting 5-tap kernel with either 64 or 32 phases.

7.7.5.2.2.2.1 Interpolation/Resampling

Figure 7-115 illustrates the interpolation principle. The assumptions are that the input pixels are evenly spaced. The distance between each input pixel is assumed to be 1. The magnification ratio is given by 64/N and p/64 is the initial phase of the output data. The output pixels are evenly spaced as well. The distance between each output pixel is given by N/64 (in the example below, N > 64). The position of the n-th output pixel is given by (n x N + p) / 64.

Copyright © 2026 Texas Instruments Incorporated

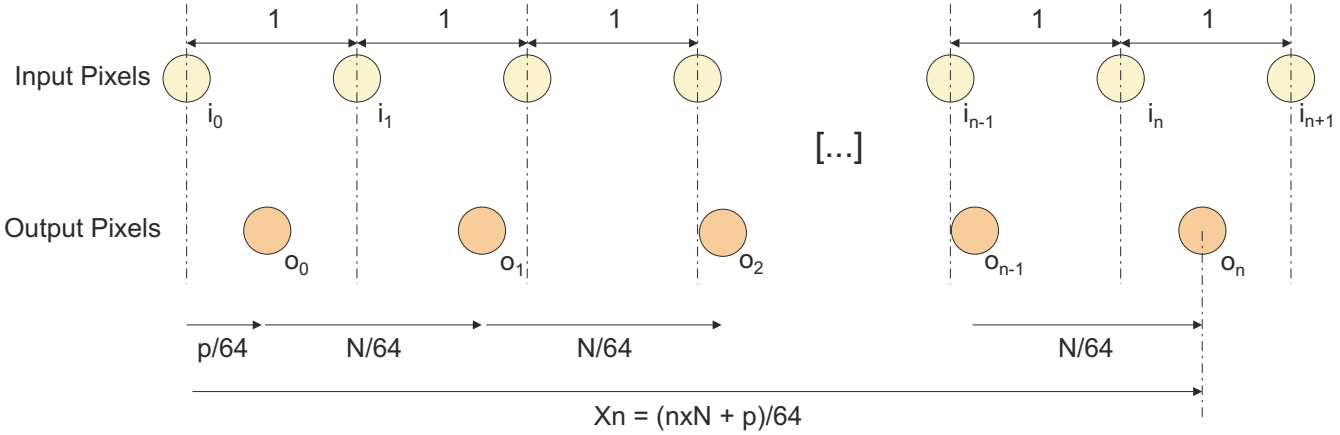

Figure 7-115. Interpolation Principle

Figure 7-116 illustrates the interpolation principle at the n-th output pixel (on) at position x_n. Interpolation method with m and d parameters, are described as:

m = floor((n x N + p) / 64)

d = ((n x N + p) / 64) - m

Figure 7-116 illustrates the concept when the filters are configured in 4-tap mode for non-integer rescaling (the first coefficient corresponding to O_{m-2} is set to zero).

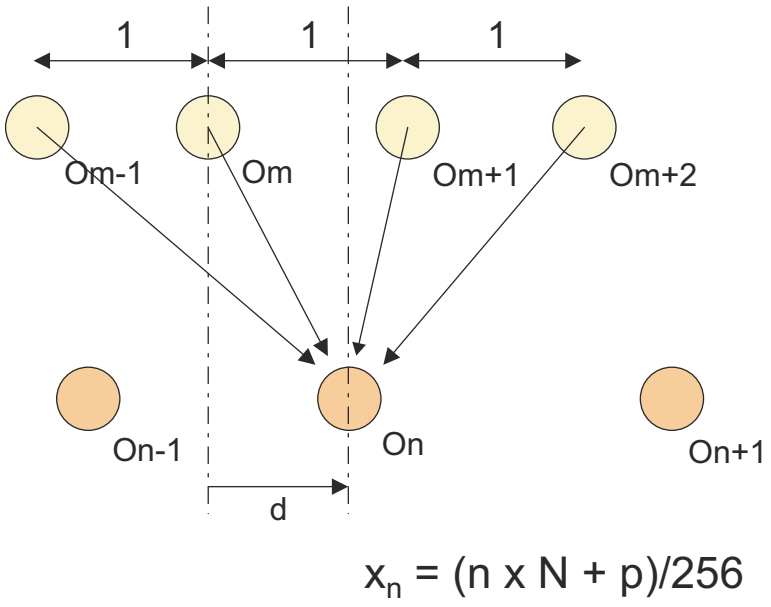

Figure 7-116. Interpolation Process

Figure 7-117 illustrates another explanation of the concept of a Polyphase filter using a simple 2-tap linear filter in a design which supports 5 phases.

Copyright © 2026 Texas Instruments Incorporated

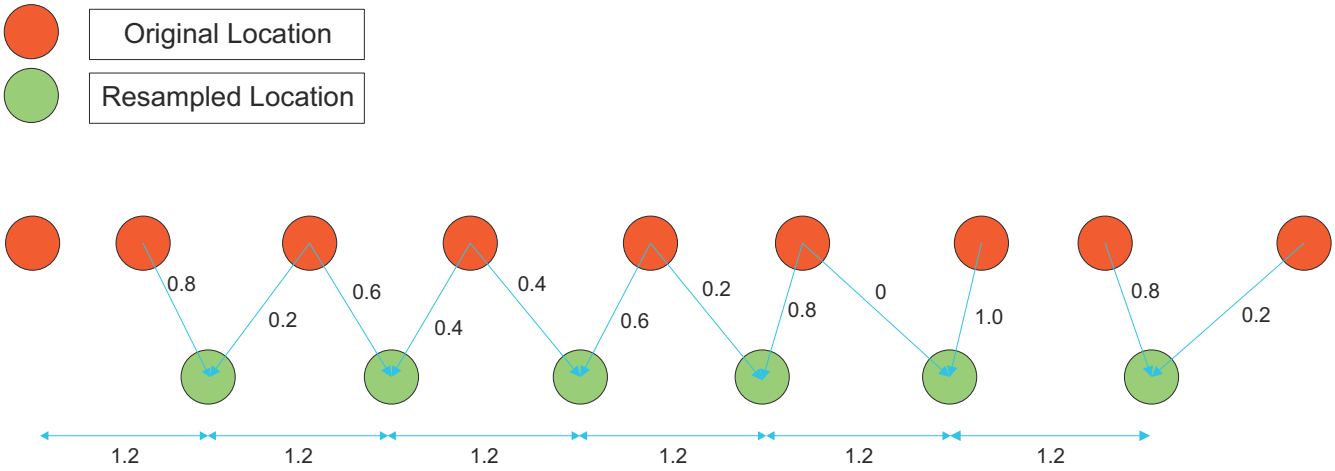

Figure 7-117. Polyphase Filtering

For each one of the 5 phases, the weights (or filter coefficients) are different and after the 5 phases the weights start repeating, see Figure 7-117.

Figure 7-118 depicts the architecture for the independent polyphase filter unit.

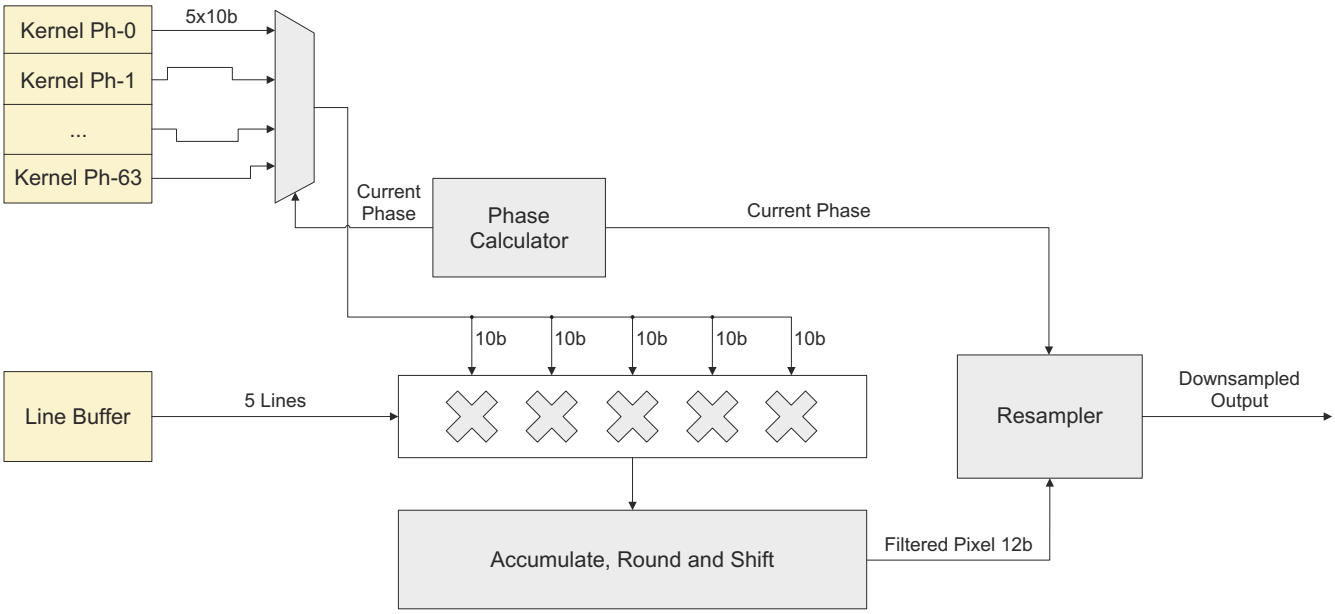

Figure 7-118. Polyphase Filter Unit

Both the horizontal and vertical filter described earlier are an instance of the Polyphase filter unit, though only the vertical filter requires line memories (implemented in SL2 memory space). In all, there will be 20 instances of the Polyphase filter unit, 2 filters per channel and 10 total channels in the VPAC_MSC module.

7.7.5.2.2.2.2 Phase Calculation and Re-sampler

The phase calculation block calculates the current phase which in turn is used for selecting the right coefficient set and for the output qualifier in the Re-sampler block. The Re-sampler engine then decides whether or not the output created by the interpolation unit is a valid output or not.

Copyright © 2026 Texas Instruments Incorporated

7.7.5.2.2.2.3 Shared Coefficient Buffers

The MSC module supports up to 4 sets of multi-phase coefficients for generic non-integer resizing and up to 10 sets of single-phase coefficients (5x1 entries) for Octave generation and integer resizing applications. The multi-phase coefficients can also be configured in one of two following options:

- 4 sets of 5-tap x 32 phase coefficients
- 1 set of 5-tap x 64 phase coefficients and 2 sets of 5-tap x 32 phase coefficients
- 2 sets of 5-tap x 64 phase coefficients

The 32 phase configuration option allows using independent coefficients for vertical and horizontal resizer to achieve aspect ratio change during the scaling.

7.7.5.2.2.2.4 Border Pixel Padding

The MSC module replicates missing lines and pixels at top/bottom and left/right sides of the input frame for non-interleaved (luma) and interleaved (chroma) data.

The missing lines at the top/bottom are replicated in the LSE sub-module prior to the vertical scaler and the missing pixels at the left/right sides of each line are replicated in the core prior to the horizontal scaler. For more information about LSE module, see *Load Store Engine (LSE)*.

Replication scheme simply repeats the edge line or pixel to create missing lines/pixels. Figure 7-119 shows horizontal pixel replication.

Figure 7-119. Horizontal Pixel Replication

If a scaling is performed on a sub-frame (ROI) within the input frame, no replicated lines/pixels will be used since the lines/pixels outside the sub-frame are already present in the input frame.

For interleaved data format, the horizontal replication is done separately for U and V data. For U-data, edge U-pixel will be replicated. For V-data, edge V-pixel will be replicated. There is no distinction in the vertical edge padding.

7.7.5.2.2.3 ROI Handling

- ROI supported during scaling generation
  - Only one ROI at Input Frame and one ROI at Output frame per scale
  - ROI definitions (for input as well as all output scales) can be changed at every input frame under software control.
  - ROI for each scale (for output) can be different among scales (as well as with respect to the input). It is set under software Control.
  - The key purpose of ROI is DDR bandwidth reduction. There is additional help by reduction on processing power on DSP and hardware.
- The input ROI is a superset area considering following two scenarios.
  - Multiple ROIs in given Input Frame, if there are multiple ROI for input frame
  - Input Frame area from Overlapped ROI across scales

Figure 7-120 shows an example of multiple ROIs in the source superset ROI area.

Copyright © 2026 Texas Instruments Incorporated

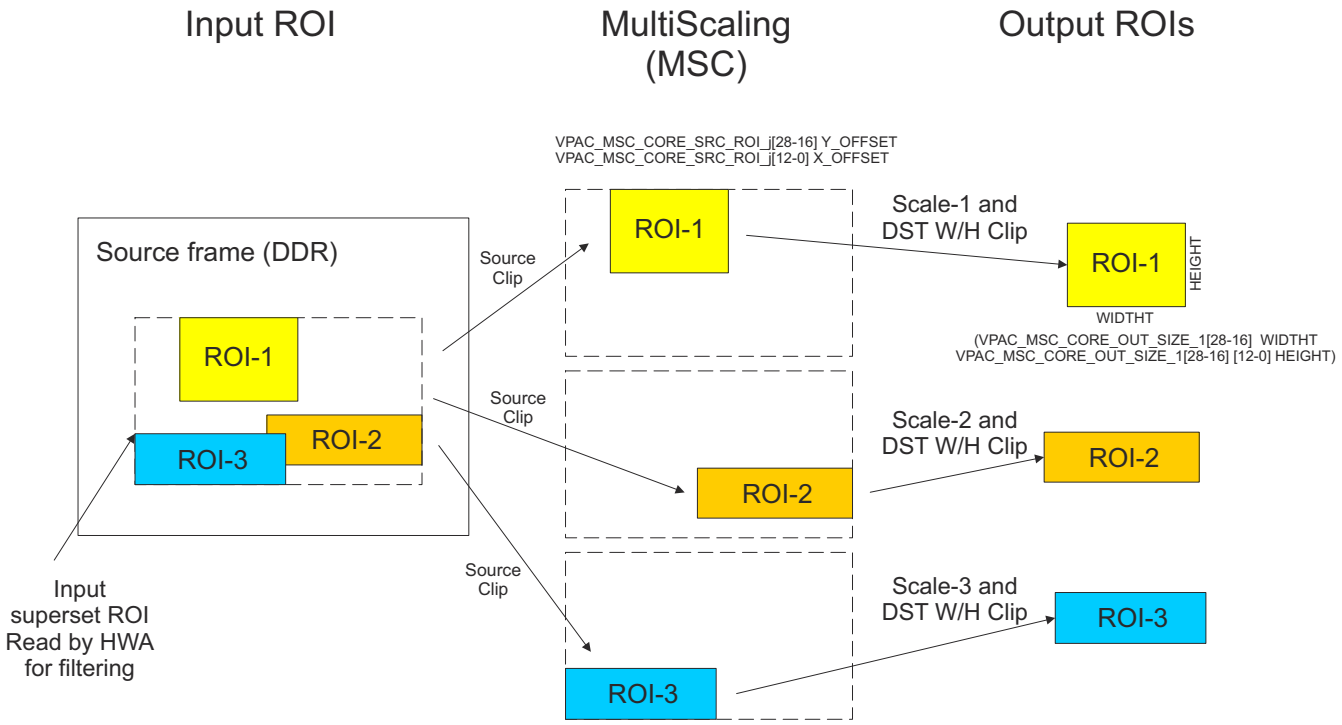

Figure 7-120. Multiple-ROI Support Illustration

Figure 7-121 illustrates another application of generating output ROIs with different scales from a common source region.

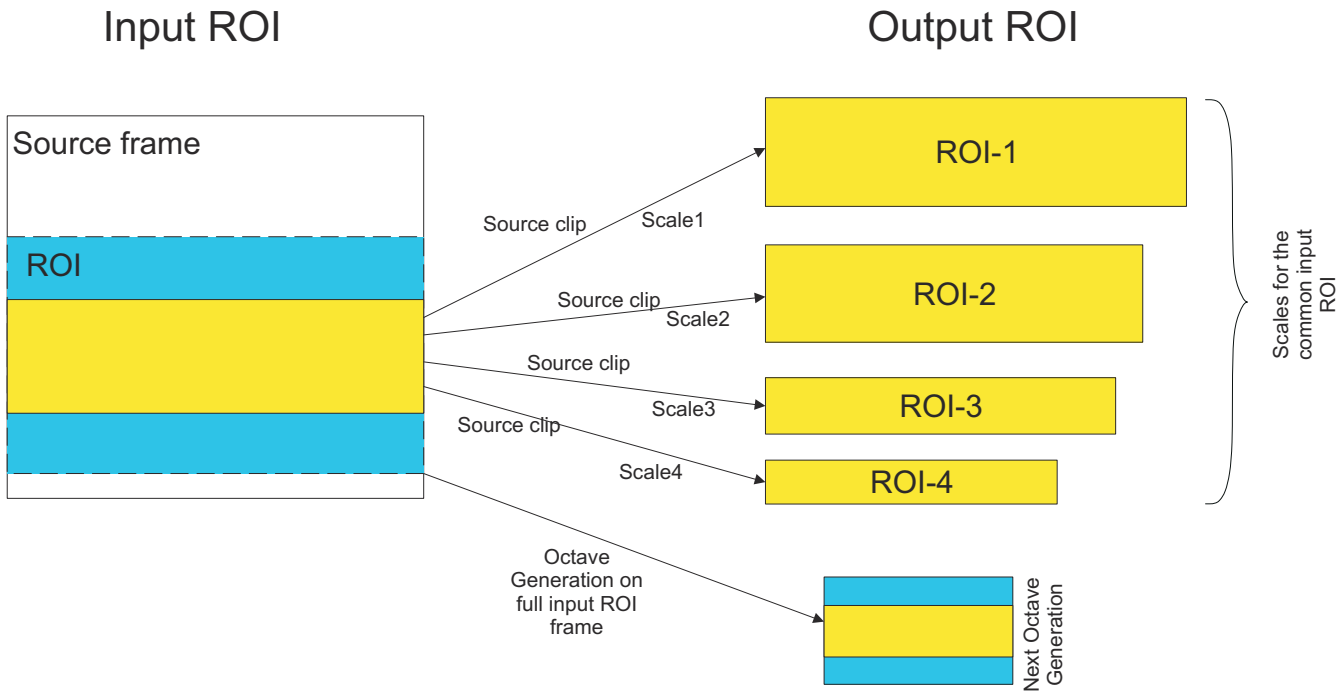

Figure 7-121. Multiple-ROI From a Common Source ROI

By defining output ROIs, only the data within ROI in the “superset ROI” scaled output image is saved thus reducing the DDR traffic significantly.

Note

MSC supports both NV12 and NV21 chroma component ordering. Since there is no color processing, the ordering of Cb and Cr is irrelevant. Simply, if a NV12 chroma plane is the input, the output will be a NV12 chroma plane.

12-bit unpacked format (16-bit container) with LSB/MSB alignments is shown below

Table 7-124 and Table 7-125 show the pixel data memory organization for YUV420 (2-plane 12-bit unpacked format – LSB aligned)

7.7.5.3 MSC Interrupt Conditions

7.7.5.3.1 CPU Interrupts

Table 7-128 lists the interupts generated by the MSC module.

Table 7-128. Interrupts

Interrupt	Type	Description
VPAC_MSC_LSE_FR_DONE_EVT_0	Pulse	Frame Processing complete for all filters in the processing thread 0.
VPAC_MSC_LSE_FR_DONE_EVT_1	Pulse	Frame Processing complete for all filters in the processing thread 1.
VPAC_MSC_LSE_SL2_RD_ERR	Pulse	Set whenever there is an error response on VBUSM read command request for any input channel
VPAC_MSC_LSE_SL2_WR_ERR	Pulse	Set whenever there is an error response on VBUSM write command request for any output channel

Copyright © 2026 Texas Instruments Incorporated

All interrupts are single pulse event signals that are mapped to the VPAC level interrupt aggregation logic. The MSC has no mask/set/clear registers for these events. For more information see Section 7.7.2, *VPAC Subsystem*.

7.7.5.3.2 Interrupt Event Description

7.7.5.3.2.1 VPAC_MSC_LSE_FR_DONE_EVT_0/1 Events

These events are generated when all filters associated with the thread 0 or 1 complete the frame processing. This is set when input EOF (end of frame) event and output EOF (end of frame) events are detected.

7.7.5.3.2.2 VPAC_MSC_LSE_SL2_RD_ERR Interrupt Event

This event is generated whenever the VBUSM read status is something other than 0 (success).

The VPAC status register VPAC_MSC_STATUS_ERROR[4-0] VM_RD_ERR stores the last non-zero RSTATUS value and the input channel number for user to see what type of error has occurred on which channel.

Table 7-129. Encoding for RSTATUS

RSTATUS	Meaning
0	Success
1	Addressing error
2	Protection error
3	Timeout error
4	Data error
5	Unsupported Addressing Mode error
6	RESERVED
7	Exclusive read fail

7.7.5.3.2.3 VPAC_MSC_LSE_SL2_WR_ERR Interrupt Event

This event is generated whenever the VBUSM write status is something other than 0 (success).

The VPAC status register VPAC_MSC_STATUS_ERROR[14-8] VM_WR_ERR stores the last non-zero WSTATUS value and the output channel number for user to see what type of error has occurred on which channel.

Table 7-130. Encoding for WSTATUS

WSTATUS	Meaning
0	Success
1	Addressing error
2	Protection error
3	Timeout error
4	Data error
5	Unsupported Addressing Mode error
6	RESERVED
7	Exclusive write fail

7.7.5.4 MSC Performance

Since the resizer performs only downscaling operations, the throughput of scaler is mostly dictated by the input processing rate – 1 input pixel per 1 clock cycle. Once the data is made available to the scaler filter after the initial set up and data fetching, the scaler should be fully active except for few cycles at the end of each line to flush the line.

If a processing thread is performing a pyramid generation only, the vertical line skip feature can be enabled to reduce the frame processing time approximately by ½.

Copyright © 2026 Texas Instruments Incorporated

7.7.5.5 MSC Clocking

Complete VPAC_MSC module operates on single clock - VPAC0_MSC_CLK.

7.7.5.6 MSC Reset

VPAC_MSC has one synchronous active low reset input. The entire module is reset by this reset.

7.7.5.7 MSC Programmer's Guide

7.7.5.7.1 Programming Model

7.7.5.7.1.1 MSC Programming Guidelines

MSC does not support shadow registers for its configuration registers. All changes must be done prior to the HTS.INIT request for a frame processing.

Input and output channels are individually enabled. It is expected that at least one input and output channels are enabled for each HTS thread enabled.

The MSC does not check for proper programming of all configuration parameters. It is strictly software responsibility to ensure programming of MSC (Core and LSE) registers do not cause conflict with each other.

7.7.5.7.1.2 MSC_Core Programming Details

All filters enabled for a multi-scaling thread are programmed via:

- VPAC_MSC_CORE_CFG_j[0] FILTER_MODE; Coefficient Set Selection - VPAC_MSC_CORE_CFG_j[3-2] HS_COEF_SEL, VPAC_MSC_CORE_CFG_j[5-4] VS_COEF_SEL, VPAC_MSC_CORE_CFG_j[10-7] SP_HS_COEF_SEL, VPAC_MSC_CORE_CFG_j[15-12] SP_VS_COEF_SEL; and filter tap size parameters VPAC_MSC_CORE_CFG_j[11] SP_VS_COEF_SRC and VPAC_MSC_CORE_CFG_j[6] SP_HS_COEF_SRC.
- Coefficients set in VPAC_MSC_CORE_C210_j, VPAC_MSC_CORE_C43_j, VPAC_MSC_CORE_C210_j_k, VPAC_MSC_CORE_C43_j_k registers.
- ROI source offset - VPAC_MSC_CORE_SRC_ROI_j[28-16] Y_OFFSET and VPAC_MSC_CORE_SRC_ROI_j[12-0] X_OFFSET, and size. The size of ROI depends on the X and Y offsets. For full-size set the offsets to 0. Note that the ROI_SIZE may or may not be same as the MSC frame size (set in MSC_FRAME_SIZE_j[28-16] HEIGHT and MSC_FRAME_SIZE_j[12-0] WIDTH) - depending on whether ROI is full or sub-frame sized.
- Output size - VPAC_MSC_CORE_OUT_SIZE_j[28-16] HEIGHT and VPAC_MSC_CORE_OUT_SIZE_j[12-0] WIDTH.
- Filter parameters - VPAC_MSC_CORE_FIRINC_j[14-0] HS, VPAC_MSC_CORE_FIRINC_j[30-16] VS, VPAC_MSC_CORE_ACC_INIT_j[27-16] VS, and VPAC_MSC_CORE_ACC_INIT_j[11-0] HS.

Filter thread mapping is done with output channel configuration parameters (MSC_BUF_CFG_j[7] THREAD_MAP). Specifying the mapping in one register for each channel prevents any resource conflict.

7.7.5.7.1.3 MSC_LSE Programming Details

Two processing threads can be activated independently.

7.7.5.7.1.3.1 Input Thread Configuration:

1. Pixel Data Format
   a. VPAC_MSC_LSE_SRC_CFG_j[1-0] PIX_FMT_PW, VPAC_MSC_LSE_SRC_CFG_j[3-2] PIX_FMT_CNTRSZ, and VPAC_MSC_LSE_SRC_CFG_j[4] PIX_FMT_ALIGN parameters define the pixel input data format for all input channels of the thread.
   b. Common data formats:
      i. Fully packed 12-bit: PIX_FMT_PW = 1, PIX_FMT_CNTRSZ = 1, PIX_FMT_ALIGN = 0
      ii. Fully packed 8-bit: PIX_FMT_PW = 0, PIX_FMT_CNTRSZ = 0, PIX_FMT_ALIGN = 0

2. Pixel Input Matrix Configuration

Copyright © 2026 Texas Instruments Incorporated

a. VPAC_MSC_LSE_SRC_CFG_j[15-12] KERN_LN_OFFSET defines the starting line offset number of the input pixel matrix (for 5-tap filter configuration, offset = 0, for 4-tap configuration, offset = 1)
b. VPAC_MSC_LSE_SRC_CFG_j[11-8] KERN_SZ_HEIGHT defines the height of the input pixel matrix (for example, MSC = 5, VISS = 1)
c. VPAC_MSC_LSE_SRC_CFG_j[21-19] KERN_TPAD_SZ, and VPAC_MSC_LSE_SRC_CFG_j[18-16] KERN_BPAD_SZ defines the number of padding lines required at top and bottom of the frame (for example, for 5-tap filter configuration for MSC, both of these parameters are set to 2. For 4-tap filter configuration for MSC, TPAD_SZ =1 while BPAD_SZ = 2).

3. Source Frame Size
   a. VPAC_MSC_LSE_SRC_FRAME_SIZE_j[28-16] HEIGHT and VPAC_MSC_LSE_SRC_FRAME_SIZE_j[12-0] WIDTH – define the width and height (pixels/lines) of the source video frame.
4. Source SL2 Circular Buffer Configuration
   a. VPAC_MSC_LSE_SRC_BUF_ATTR_j[15-6] BUF_STRIDE – defines the line stride size (must be 64 byte multiple)
   b. VPAC_MSC_LSE_SRC_BUF_ATTR_j[24-16] CBUF_SIZE – define the size of the circular buffer in the SL2 (number of lines)
   c. VPAC_MSC_LSE_SRC_BUF_ATTR_j[31-25] START_NIB_OFFSET – defines the line start offset in smaller resolution (start address within the first SL2 512-bit word in 4-bit resolution).
5. Source BA and Enable Configuration
   a. VPAC_MSC_LSE_SRC_i_BUF_BA_y[23-6] ADDR – defines the SL2 base address of the Circular buffer for the input channel. VPAC_MSC_LSE_SRC_i_BUF_BA_y[31] ENABLE – enables the input channel.

7.7.5.7.1.3.2 Output Channel Configuration

1. Pixel Data Format
   a. VPAC_MSC_LSE_DST_BUF_CFG_j[1-0] PIX_FMT_PW, VPAC_MSC_LSE_DST_BUF_CFG_j[3-2] PIX_FMT_CNTRSZ, and VPAC_MSC_LSE_DST_BUF_CFG_j[4] PIX_FMT_ALIGN parameters define the pixel output data format for this output channel.
   b. Common data formats:
      i. Fully packed 12-bit: PIX_FMT_PW = 1, PIX_FMT_CNTRSZ = 1, PIX_FMT_ALIGN = 0
      ii. Fully packed 8-bit: PIX_FMT_PW = 0, PIX_FMT_CNTRSZ = 0, PIX_FMT_ALIGN = 0
2. Output Thread Map
   a. VPAC_MSC_LSE_DST_BUF_CFG_j[7] THREAD_MAP defines the output channel thread mapping.
3. Output SL2 Circular Buffer Configuration
   a. VPAC_MSC_LSE_DST_BUF_ATTR0_j[15-6] BUF_STRIDE – define the line stride size (must be 64 byte multiple)
   b. VPAC_MSC_LSE_DST_BUF_ATTR0_j[24-16] CBUF_SIZE – define the size of the circular buffer in the SL2 (number of lines)
4. Base Address and Channel Enable:
   a. VPAC_MSC_LSE_DST_BUF_BA_j[23-6] ADDR – defines the SL2 base address of the Circular buffer for this output channel.
   b. VPAC_MSC_LSE_DST_BUF_BA_j[31] ENABLE – enables this output channel.

7.7.5.7.1.4 MSC HTS Programming Details

There is no configuration required for HTS interface in the MSC_HWA. All programming is done in the separate HTS module. It is expected that at least one input and output channel is enabled for each HTS thread. For more details on programming HTS, see *Hardware Accelerator (HWA) Thread Scheduler (HTS)*.

Copyright © 2026 Texas Instruments Incorporated

7.7.5.7.1.5 MSC Data Transfer Programming Details

Refer to *VPAC Subsystem Programmer's Guide*.

7.7.5.7.1.6 LSE Interrupt Programming

MSC does not have any interrupt MASK/SET/CLEAR registers . Interrupts are pulse output events that go to the VPAC top level interrupt aggregation logic. For more information about the aggregation logic, see Section 7.7.2, *VPAC Subsystem*.

MSC does, however, provide a set of statuses for VBUSM interface errors. These status are mapped to VPAC_MSC_STATUS_ERROR and they are cleared by writing all 1's to the status bit field.

7.7.5.7.2 Initialization Sequence

For details, see Section 7.7.2, *VPAC Subsystem Level*.

7.7.5.7.3 Real-Time Operating Requirements

For details, see Section 7.7.2, *VPAC Subsystem Level*.

7.7.5.7.4 Power Up/Down Sequence

For details, see Section 7.7.2, *VPAC Subsystem Level*.

7.8 Depth and Motion Perception Accelerator (DMPAC)

This chapter describes the Depth and Motion Perception Accelerator (DMPAC) in the device.

7.8.1 DMPAC Overview

The Depth and Motion Perception Accelerator (DMPAC) is a power efficient hardware accelerator that computes dense stereo depth maps (*depth*) and dense optical flow vectors (*motion*) from camera inputs.

The image/video sensor-based environmental perception (also known as scene understanding) is at the core of many emerging applications in automotive, industrial and consumer electronics. Typically, this involves detection of all objects in the scene along with their 3D position and motion with regards to the observer or the car by analyzing one or many related input video streams. Various computer vision algorithms are used to achieve these tasks.

A very robust method of obtaining the 3D depth from images is to use two cameras in a stereo setup - two cameras with known relative positions and camera parameters. The two images of the same scene, captured from two different camera poses/perspectives, are analyzed to find disparities among every pixel positions in the images. This is known as the Stereo Disparity map. The disparity values of every pixel can be used to obtain the 3D positions of the object/space they belong to via triangulation.

On the other hand, by analyzing two images from a single camera, captured at two different time instances (that is, two temporal frames in a video), one can determine where each pixel in a past frame moved to in the future frame. This is known as the Optical Flow vector. The flow vectors for each pixel position can be used to obtain 3D structure of the scene, identify moving objects and determine their relative speed and direction of motion.

The DMPAC is dedicated to the aforesaid image processing tasks. The stereo and optical flow processing is partitioned into two top level sub-blocks: the Dense Optical Flow (DOF) engine and the Stereo Disparity Engine (SDE). The DOF and SDE blocks share a common shared local memory, DMA, external messaging and control infrastructure.

7.8.1.1 DMPAC Features

The DMPAC supports the following main features:

- Input image resolution up to 2 MPix with maximum horizontal resolution of up to 2048 pixels and maximum vertical resolution of up to 1024 pixels
- Input pixel format of 12-bit fully packed luminance data, and other formats using the integrated Format Conversion (FOCO) module
- Pixel level output packed in 16bpp and 32bpp formats for stereo disparity estimates and optical flow estimates, respectively
- Simultaneous operation of SDE and DOF, each processing inputs of up to 1 MPix image resolution (1 MPix = 1280 × 720 pixels)
- Resolution vs. frame rate scalability (higher frame rate at lower resolution)
- A Dense Optical Flow (DOF) engine: The DOF engine implements Texas Instruments' proprietary algorithm for estimation/calculation of the optical flow between the input image pair. The algorithm uses hierarchical coarse-to-fine block search strategy leveraging image pyramids in which proprietary binary pixel descriptors are used for pixel correspondence determination. In the scheme accuracy and smoothness of the flow map is enforced using optical flow estimates of the causal neighbors of a pixel in the given and higher (lower resolution) pyramid level (pixels are processed in raster scan order in a pyramid level to refine existing optical flow estimates). The DOF engine supports:
  - Optical flow vector lengths up to +/- 191 pixels in horizontal direction and +/- 62 pixels in vertical direction for each input pixel
  - Dense flow vector map for each input pixel
  - Optical flow vector precision of $1/16^{th}$ of inter pixel distance
  - Post filtering of the optical flow estimates using 2D median filtering
  - 16 level confidence score for every output flow vector
- A Stereo Disparity Engine (SDE): The SDE implements Texas Instruments' proprietary algorithm in order to find the disparity map between the input image pair. The SDE supports:

Copyright © 2026 Texas Instruments Incorporated

  - Disparity search range (SR) of 64/128/192. It can support either "0 to SR-1" or "-3 to SR-4"
  - 1/16th pixel accurate sub-pixel level disparity estimate
  - Disparity estimate post processing using 2D median filtering
  - 8 level confidence score for each disparity output
- Common top level infrastructure:
  - Shared Level 2 (SL2) memory sub-system, which serves both DOF and SDE blocks, along with the FOCO modules when required as an intermediate storage exchange data across sub-modules (FOCO to DOF/SDE) and from DDR/System Memory
  - A Unified Transfer Controller (UTC), which serves as a DMA engine
  - Messaging and control mechanism via a Hardware Thread Scheduler (HTS) block
  - A Counter, Timer and System Event Trace (CTSET) module, which provides event tracing capability for the SDE and DOF hardware threads

The DMPAC does not support (but relies on other HWAs/processors on the SoC to perform these tasks):

- Epipolar rectification of the stereo input images
- Image pyramid generation for the optical flow input images

7.8.1.2 DMPAC Not Supported Features

The DMPAC does not support the following features:

- Arbitrary binary feature descriptor as input
- Flexible block matching on any image/feature vector plane
- Standalone use of any of the DMPAC internal modules by any SoC level resources, even when the DMPAC is not in use

The following processing steps, although essential parts of the stereo and optical flow algorithms supported inside DMPAC, are expected to be handled outside the DMPAC module:

- Epipolar Rectification on both the stereo input image streams
- 6 levels (including base) of Image Pyramid generation on the optical flow input image stream

7.9 Graphics Accelerator (GPU)

This chapter describes the integration of the Graphics Processing Unit (GPU) subsystem in the device.

7.9.1 GPU Overview

The Graphics Processing Unit (GPU) accelerates 3-dimensional (3D), 2-dimensional (2D) graphics, and compute applications.

The GPU is based on the PowerVR® BXS 4-64 MC1 core from Imagination Technologies.

7.9.1.1 Features Supported

- Base architecture, fully compliant with the following APIs:
  - OpenGL ES 3.2
  - OpenCL 1.2 EP
  - Vulkan 1.2
- Tile-based deferred rendering architecture for 3D graphics workloads, with concurrent processing of multiple tiles
- Support for DRM security
- Support for GPU virtualization
  - Up to 8 virtual GPUs
  - Separate IRQ for each OSID
- Multi-threaded Unified Shading Cluster (USC) engine incorporating pixel shader, vertex shader and GP-GPU (compute shader) functionality
- USC incorporates an ALU architecture with high SIMD efficiency
- Fully virtualized memory addressing (up to 64 GB address space), supporting unified memory architecture
- Fine-grained task switching, workload balancing and power management

Copyright © 2026 Texas Instruments Incorporated

- Advanced DMA driven operation for minimum host CPU interaction
- 256KB System Level Cache (SLC)
- Specialized Texture Cache Unit (TCU)
- Compressed Texture Decoding
- Lossless data compression (PVRGC) - The PowerVR's geometry compression, which is performed in the Geometry Processing phase of the 3D graphics workload.
- Dedicated RISC-V processor for firmware execution
- Separate power island for the firmware processor for low latency power domain transitions
- On-Chip Performance, Power and Statistics Registers.
- Resolution Support
  - Frame buffer max size = 8K × 8K
  - Texture max size = 8K × 8K
- Anti-aliasing
  - Maximum 4× multisampling
- Performance
  - Floating Point Operations (F32) - 64 operations per clock
  - Floating Point Operations (F16) - 128 operations per clock
  - Texture performance - 4 texels per clock (@32 BPP)
  - Pixel performance - 4 pixel(s) per clock (@32 BPP)
  - Geometry Performance - 0.25 triangles per clock
  - Max performance
    - ~50 GFLOPS, 3.2 GPix/s @ 800MHz

Note

Some features may not be available. See *Module Integration* for more information.

7.9.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

Chapter 8

Inter-processor Communication Scheme (IPC)

Device has multiple hardware mechanisms to provide inter-processor level communication.

8.1 Mailbox 790
8.2 Spinlock 797
8.3 Secure Proxy (SEC_PROXY) 801

Copyright © 2026 Texas Instruments Incorporated

8.1 Mailbox

This chapter describes the Mailbox module of the device.

8.1.1 Mailbox Overview

Mailbox module serves to facilitate the communication between the various on-chip processors of the device by providing a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors (users) through a set of registers and associated interrupt signals.

8.1.1.1 Mailbox Features

Each mailbox module supports the following features:

- Parameters configured at design time:
  - Number of mailbox clusters
    - Each mailbox cluster has the same configuration
    - Clusters are accessed via separate VBUS regions. Clusters can be treated as mailbox module instances.
  - Number of users
  - Number of mailbox message queues
  - Number of messages (FIFO depth) for each message queue
- 32-bit message width
- Partial writes do not advance the FIFO pointers
- Message reception and queue-not-full notification using interrupts
- Non-intrusive emulation

Note

Some features may not be available. See *Module Integration* for more information.

Copyright © 2026 Texas Instruments Incorporated

8.1.2 Mailbox Functional Description

The mailbox module provides a means of communication through message queues among the users. The individual mailbox modules, or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQ_ENABLE_SET_j (or MAILBOX_IRQ_ENABLE_CLR_j) register.

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

Each MAILBOX_IRQ_STATUS_RAW_j/MAILBOX_IRQ_STATUS_CLR_j interrupt status register corresponds to a particular user.

8.1.2.1 Mailbox Block Diagram

Figure 8-1 shows the mailbox internal block diagram.

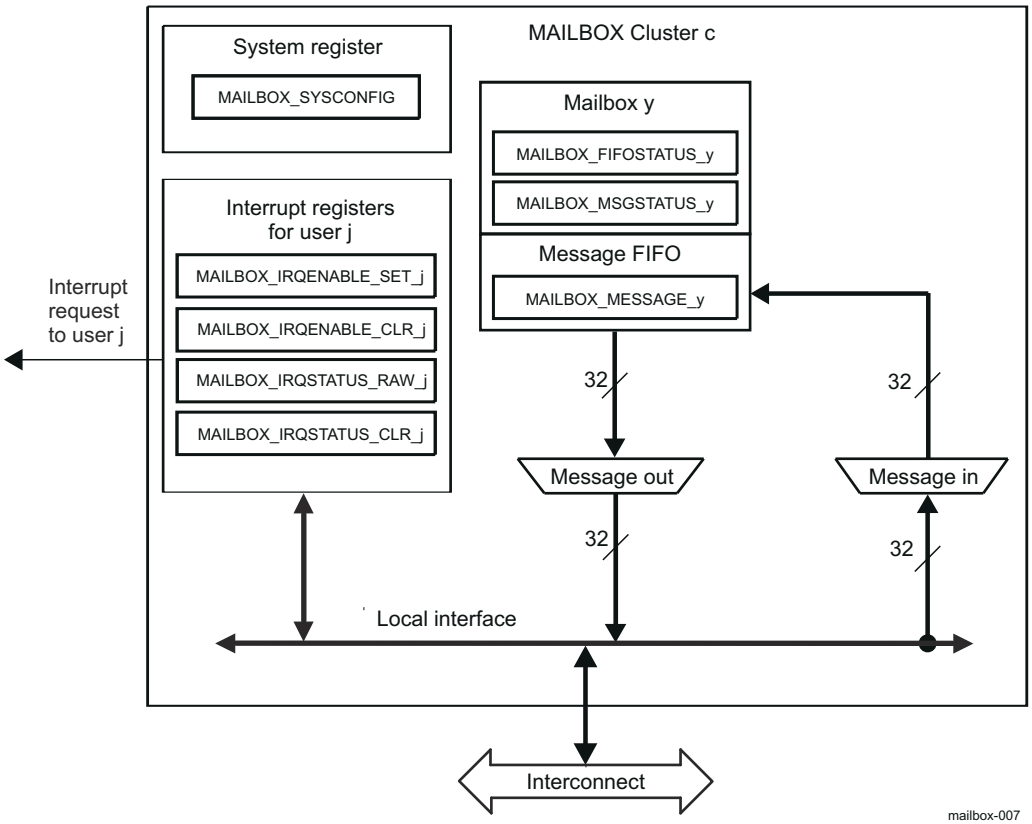

Figure 8-1. Mailbox Block Diagram

c = 0 to 11

j = 0 to 3

y = 0 to 15

8.1.2.2 Mailbox Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

Copyright © 2026 Texas Instruments Incorporated

8.1.2.3 Mailbox Power Management

The clkstop_idle will be asserted if all of the following are true:

- The VBUSP interface is inactive
- All mailboxes are empty
- There are no enabled events or outstanding interrupts

An enabled event means there is pending action required from one of the users, and it means one or more mailboxes still expect data.

8.1.2.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

Table 8-1 lists the event flags, and their mask, that can cause module interrupts.

Table 8-1. Interrupt Events

Non-Maskable Event Flag(1)	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQ_STATUS_RAW_j[0+y*2] NEWMSGSTATUSMBy	MAILBOX_IRQ_STATUS_CLR_j[0+y*2] NEWMSG_STATUSMBy	MAILBOX_IRQ_ENABLE_CLR_j[0+y*2] NEWMSG_STATUSMBy	MAILBOX_IRQ_ENABLE_SET_j[0+y*2] NEWMSG_STATUSMBy	Mailbox *y* receives a new message.
MAILBOX_IRQ_STATUS_RAW_j[1+y*2] NOTFULLSTATUSMBy	MAILBOX_IRQ_STATUS_CLR_j[1+y*2] NOTFULLSTATUSMBy	MAILBOX_IRQ_ENABLE_CLR_j[1+y*2] NOTFULLSTATUSMBy	MAILBOX_IRQ_ENABLE_SET_j[1+y*2] NOTFULLSTATUSMBy	Mailbox *y* message queue is not full.

(1) MAILBOX_IRQ_STATUS_RAW_j register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQ_STATUS_CLR_j register.

Writing a logical 1 in a bit of the MAILBOX_IRQ_STATUS_CLR_j register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQ_STATUS_RAW_j register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQ_ENABLE_SET_j register. Events are reported in the appropriate MAILBOX_IRQ_ENABLE_CLR_j and MAILBOX_IRQ_STATUS_RAW_j registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQ_ENABLE_CLR_j register. Events are only reported in the appropriate MAILBOX_IRQ_STATUS_RAW_j register.

In case of the MAILBOX_IRQ_STATUS_RAW_j register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

8.1.2.5 Mailbox Assignment

8.1.2.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQ_ENABLE_SET_j register. The receiver reads the MAILBOX_MESSAGE_y register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFO_STATUS_y and/or MAILBOX_MSG_STATUS_y registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

Copyright © 2026 Texas Instruments Incorporated

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQ_ENABLE_SET_j register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFO_STATUS_y or MAILBOX_MSG_STATUS_y registers
- Write the message to the corresponding MAILBOX_MESSAGE_y register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQ_ENABLE_SET_j register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQ_STATUS_CLR_j register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQ_STATUS_CLR_j register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

8.1.2.6 Sending and Receiving Messages

8.1.2.6.1 Description

When a 32-bit message is written to the MAILBOX_MESSAGE_y register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the MAILBOX_FIFO_STATUS_y register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX_MESSAGE_y register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_y register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSG_STATUS_y register.

8.2 Spinlock

This chapter describes the Spinlock module of the device.

8.2.1 Spinlock Overview

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device.

The Spinlock module implements 256 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 8-3 shows an overview of the Spinlock module.

Figure 8-3. Spinlock Overview

Note

Some features may not be available. See *Module Integration* for more information.

8.2.2 Spinlock Functional Description

8.2.2.1 Spinlock Software Reset

The Spinlock module can be reset by software through the SPINLOCK_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The SPINLOCK_SYSTATUS[0] RESETDONE bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

8.2.2.2 Spinlock Power Management

The Spinlock module supports the Power Idle interface. Software must arrange to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

1. Software must check that all controllers that may be using the Spinlock module are either:
   a. Already powered off (all in-use flags are 0)
   b. Notified that Spinlock is not available and the notification is acknowledged
2. If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 32 locks can be read from the SPINLOCK_SYSTATUS register. If any locks are held, they are orphaned because they are not held by any controller that is still active. Alternatively, you may decide to wait a timeout period to allow any active controller to clean up its locks before powering down.

The Spinlock module may now be powered off.

8.2.2.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).

Copyright © 2026 Texas Instruments Incorporated

2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

8.2.2.4 Spinlock Functional Operation

The Spinlock module supports 256 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK_LOCK_REG_i[0] TAKEN bit. There are two states: Taken (SPINLOCK_LOCK_REG_y[0] TAKEN = 1) or Not Taken (SPINLOCK_LOCK_REG_y[0] TAKEN = 0), where y = 0h to FFh.

When the status of lock *y* (where y = 0 to 255) is Not Taken (free), a read from the SPINLOCK_LOCK_REG_y register returns 0 and sets the lock to Taken (locked). When the status of lock *y* is Taken, a read returns 1 and does not change the state of the lock.

A write to the SPINLOCK_LOCK_REG_y register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

Figure 8-4 shows the SPINLOCK_LOCK_REG_y register state diagram.

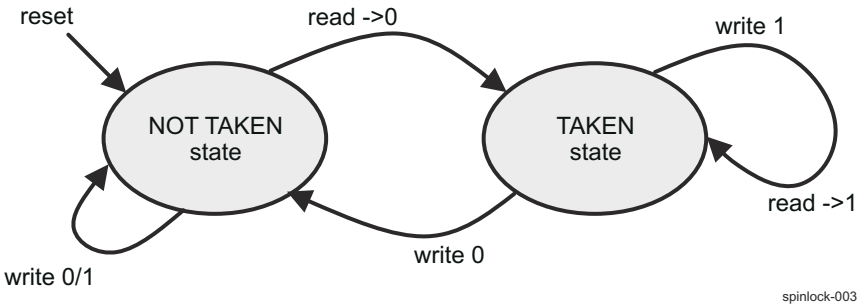

Figure 8-4. Lock Register State Diagram

Note

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

8.2.3 Spinlock Programming Guide

8.2.3.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

8.2.3.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

Table 8-10. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
LPSC	Spinlock functional and interface clock must be enabled. For more information, see *Clocking*

8.2.3.1.2 Basic Spinlock Operations

The main Spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

8.2.3.1.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK_LOCK_REG_y registers at system startup to insure that all locks are initialized to Not Taken.

Table 8-11. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = 1?	SPINLOCK_SYSTATUS[0] IU0	=1
Free the 256 locks	SPINLOCK_LOCK_REG_y[0] TAKEN (y = 0 to 255)	0x0
END		

8.2.3.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software must disable interrupts. Then it must read the SPINLOCK_LOCK_REG_y[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it must proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition must be reattempted. To prevent unknown interrupt disabled time, interrupts must be re-enabled and then disabled before reattempting to acquire the lock. Figure 8-5 shows the described above procedure.

8.3 Secure Proxy (SEC_PROXY)

The third IPC hardware mechanism is to use SEC_PROXY, which provides an IPC mechanism which carries a large message for complex communications among processors. It allows processors to read and write a message in small chunks.

There are two sets of SEC_PROXY in the device, one SEC_PROXY is dedicated for IPC for HSM M4F, and the second SEC_PROXY is for the rest. When the SEC_PROXY generates events, an IPC message is received or sent, and events are sent to interrupt aggregators before those events are converted into interrupts to the processors. The utilization of SEC_PROXY is user defined through memory map allocation. Each processor can be allocated with its own SEC_PROXY region to receive and send IPC messages.

Chapter 9

Memory Controllers

9.1 DDR Subsystem (DDRSS).....803

Copyright © 2026 Texas Instruments Incorporated

9.1 DDR Subsystem (DDRSS)

This section describes the DDR Subsystem (DDRSS) for the device.

9.1.1 DDRSS Overview

The DDR subsystem in this device comprises DDR controller, DDR PHY and wrapper logic to integrate these blocks in the device. The DDR subsystem is referred to as DDRSS0 and is used to provide an interface to external SDRAM devices which can be utilized for storing program or data. DDRSS0 is accessed via CBASS0 interconnect.

The DDRSS0 supports:

- Memory Types:
  - LPDDR4 up to @ 0.75V or 0.85V VDD_CORE
- Memory Bus Features:
  - Up to 32-bit width with in-line ECC
  - Up to 2 ranks
  - LPDDR4 densities up to 8GBytes (4GBytes each rank)
- Two System Bus Interfaces - one for real time and another for non-real time traffic:
  - 256-bit data width
  - Little endian only
  - Address aliasing prevention to block accesses to unpopulated SDRAM region
  - Clock asynchronous to DDR clock
- Configuration Bus Interface:
  - 32-bit data width
  - Linear incrementing addressing mode
  - 32-bit aligned accesses only
  - Little endian only
  - Clock asynchronous to DDR clock
- Key Features:
  - Full coherency across all commands
  - Bank interleaving
  - Priority based scheduling
  - Scheduling based on bank openness
  - Class of Service (CoS) - Three latency classes supported
  - Leaky bucket function to avoid blocking of Low Priority Thread
  - Drain function to expedite execution of reads in the controller
  - Read/write scheduling to avoid turn-around time
  - Prioritized refresh scheduling
  - Dynamic change of refresh rate via software for extended temperatures
  - Statistical counters for performance management
- SDRAM ECC Features:
  - In-line ECC
  - 64-byte ECC calculated over 512-byte data
  - Read-modify-write ECC for sub-word writes
  - Support ECC cache to improve in-line ECC performance
  - Support 64 cache-lines each 512-byte wide
  - In-line ECC performance impact shall be minimum of 12.5% for linear cached traffic
  - ECC address error logging
  - Statistical counters for counting ECC errors
- Low Power Features:
  - All power modes defined by JEDEC (clock stop for LPDDR4, self-refresh, power-down, etc.)
  - Self-refresh entry and exit via software or hardware clock stop request/acknowledge
  - System bus clock stop via hardware clock stop request/acknowledge when controller is idle

Copyright © 2026 Texas Instruments Incorporated

  - Automatic idle power saving mode when no or low activity is detected
  - DDR and system bus clock frequency change using self-refresh via software or hardware clock stop request/acknowledge
  - Turning off SoC power after DDR is put into self-refresh (DDR reset and CKE I/O retention)
  - Tri-stating of all DDR I/O cells via software while driving CKE and RESETn pins during self-refresh
  - LPDDR4 Frequency Set Point (FSP)
  - Support power switches on DDR subchip for low leakage power in low-power modesSupport power switches on DDR subchip for low leakage power in low-power modes
- Functional Safety Features:
  - VBUSM2AXI bridge AXI bus timeout
  - DDR4 command bus parity
- DDR PHY Features:
  - Automatic and software controllable initialization and calibration (ZQ) for the DDR PHY and I/O cells
  - Automatic and software controllable delay line calibrations with Voltage and Temperature (VT) compensation
  - Automatic and software controllable write levelling with VT compensation
  - Automatic read DQS gate training per rank with VT compensation
  - Automatic and software controllable DQ/DQS eye training per rank
  - Automatic and software controllable read and write data bit deskew
  - Automatic and software controllable Command/Address (CA) levelling with VT compensation for LPDDR4
  - Automatic and software controllable CA bit deskew for LPDDR4
  - Refreshes to SDRAM during leveling and training
  - No seeding requirement based on board topology for any of the leveling and training algorithms
  - Dynamic/automatic I/O Receiver disable when read transfer is not on going
  - Capability of disabling data macros and I/O cells when not in use

Note

Some features may not be available. See *Module Integration* for more information.

9.1.3 DDRSS Functional Description

9.1.3.1 Real Time and Non-Real Time Threads

The VBUSM2AXI supports two VBUSM interfaces:

- Real Time High Priority Thread (HPT)
- Non-Real Time Low Priority Thread (LPT)

HPT will have priority over LPT. In addition to the thread priority, the bridge will also reorder commands within a particular thread based on VBUSM priority. Therefore, the execution of commands from the command FIFO can be out-of-order. As a result, the read data can also be returned out-of-order.

The bridge will NOT maintain data coherency across threads. However, coherency within a particular thread will be maintained.

For low area implementation, the same FIFO resources are shared between HPT and LPT for write status and read data return interfaces. Therefore, system must ensure that there is no pushback on the write status and read data return interfaces by LPT to guarantee execution of HPT is not blocked.

9.1.3.2 Class of Service (CoS)

Commands arriving on LPT and HPT to the DDRSS0 carry the VBUSM priority whereas the DDR controller uses AXI priority. The VBUSM2AXI bridge has the following registers for flexible mapping of the VBUSM priority to DDR controllers's priority:

- Range match registers:
  - EMIF_SSCFG_V2A_R1_MAT_REG
  - EMIF_SSCFG_V2A_R2_MAT_REG
  - EMIF_SSCFG_V2A_R3_MAT_REG
- Priority map registers:
  - EMIF_SSCFG_V2A_LPT_DEF_PRI_MAP_REG
  - EMIF_SSCFG_V2A_LPT_R1_PRI_MAP_REG
  - EMIF_SSCFG_V2A_LPT_R2_PRI_MAP_REG
  - EMIF_SSCFG_V2A_LPT_R3_PRI_MAP_REG
  - EMIF_SSCFG_V2A_HPT_DEF_PRI_MAP_REG
  - EMIF_SSCFG_V2A_HPT_R1_PRI_MAP_REG
  - EMIF_SSCFG_V2A_HPT_R2_PRI_MAP_REG
  - EMIF_SSCFG_V2A_HPT_R3_PRI_MAP_REG

This allows the system to essentially create different classes of service based on the initiator (Route ID) and the priority of the commands.

Each thread has a set of corresponding Priority Map Registers to map the incoming priority on that thread to appropriate AXI priority. The default values of these registers are such that inherently the HPT traffic will have higher priority than the LPT traffic inside the controller. However, these settings can be changed via software per system needs.

The controller performs command arbitration based on AXI priority and the state of the DDR device (openness of banks, etc.). Commands with higher priority will be given execution preference over commands with lower priority. However, due to the state of the DDR device (openness of banks, etc.), a command with higher priority may not be executed before a lower priority command. Therefore, transactions within a thread can be reordered. In addition, the controller does not have any information on the thread type of the transactions. Therefore, commands can also be reordered between thread types. However, at all times the controller maintains coherency across all commands within a given thread.

Copyright © 2026 Texas Instruments Incorporated

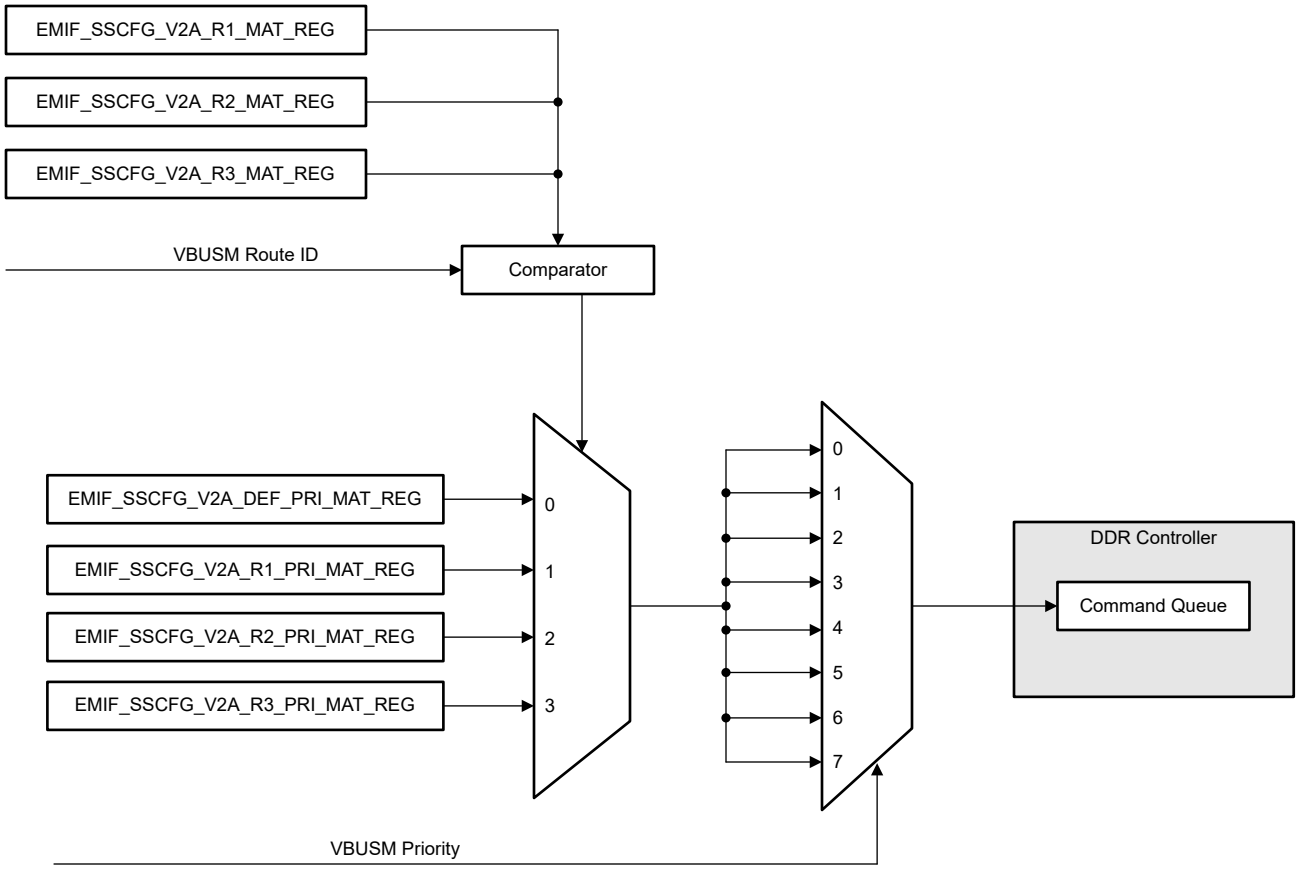

Figure 9-1. DDRSS CoS Mapping Diagram

9.1.3.3 AXI Write Data All-Strobes

The DDR controller data path is connected to the VBUSM2AXI bridge through AXI interface. To enable higher performance and lower latency, the bridge drives the AXI AWALLSTRB signal to a "1" when the AXI write data does not have any byte enable holes. This allows the DDR controller to accept and start processing the write command as soon as possible without waiting for all data. The AXI0_ALL_STROBES_USED_ENABLE bit in the DDR Controller must be set to a 0x1 to utilize this feature. The controller ignores the AWALLSTRB signal if AXI0_ALL_STROBES_USED_ENABLE is set to 0x0.

9.1.3.4 Inline ECC for SDRAM Data

For SDRAM data integrity, the VBUSM2AXI bridge supports inline ECC on the data written to or read from the SDRAM. ECC is enabled by programming the bits in the EMIF_SSCFG_ECC_CTRL_REG register. ECC is stored together with the data so that a dedicated SDRAM device for ECC is not required.

8-bit single error correction double error detection (SECDED) ECC is calculated over 64-bit data quanta. For every 512-byte data block 64 bytes of ECC is stored inline. Thus 1/9th of the total SDRAM space is used for ECC storage and the rest 8/9th is available for system use. From system point of view that 8/9th of the SDRAM data space are seen as consecutive byte addresses. Even if there are non-ECC protected regions the previously described 1/9th-8/9th rule still applies and consecutive byte addresses are seen from system point of view. Note that 8/9 of the total SDRAM space is available for system use regardless of the size of the ECC region(s). In other words, only 8/9 of the memory is available even in non-ECC regions when ECC is enabled.

The ECC is calculated for all accesses that are within the address ranges protected by ECC. The address ranges are specified through the following registers:

- EMIF_SSCFG_ECC_R0_STR_ADDR_REG
- EMIF_SSCFG_ECC_R0_END_ADDR_REG

Copyright © 2026 Texas Instruments Incorporated

- EMIF_SSCFG_ECC_R1_STR_ADDR_REG
- EMIF_SSCFG_ECC_R1_END_ADDR_REG
- EMIF_SSCFG_ECC_R2_STR_ADDR_REG
- EMIF_SSCFG_ECC_R2_END_ADDR_REG

Note that the addresses in these address range registers should be in terms of the DDRSS address space, not the SoC memory space. Even though the SoC memory space for DDR may be split into multiple regions, the DDRSS address space is continuous.

For example, if the beginning of DDR is in SoC memory space 0x8000_0000 to 0xFFFF_FFFF, this corresponds to DDRSS address space 0x00000000 to 0x7FFFFFFF. If the SoC has greater DDR address reach, even at a discontinuous address, the address range for these registers would be continuous (eg, if the next DDR address at the SoC level is 0x880000000, the corresponding address would be continuous at 0x80000000)

Note that the value programmed in the ECC range start/end registers does not include the lower 16 bits of the address. For example, to represent an address of 0x40000000, the register contents would be 0x4000.

The ECC is read and verified during reads if both the EMIF_SSCFG_ECC_CTRL_REG[0] ECC_EN and EMIF_SSCFG_ECC_CTRL_REG[2] ECC_CK bits are set to 0x1. For 1-bit ECC error, the bridge corrects the data and returns it to the requestor. Although the error is corrected on the returned data, the SDRAM is not corrected. It is responsibility of the system software to correct the ECC error at that location.

It is also responsibility of the system software to pre-load the ECC protected region with known data before functional reads and writes are performed. This can be done by writing to the SDRAM with ECC enabled (EMIF_SSCFG_ECC_CTRL_REG[0] ECC_EN = 0x1 and EMIF_SSCFG_ECC_CTRL_REG[1] RMW_EN = 0x1) and ECC check disabled (EMIF_SSCFG_ECC_CTRL_REG[2] ECC_CK = 0x0). Once the data is loaded in the SDRAM, ECC check must be enabled (EMIF_SSCFG_ECC_CTRL_REG[2] ECC_CK = 0x1) before using the DDR interface.

9.1.3.4.1 ECC Cache

The VBUSM2AXI bridge implements a 64-line deep ECC cache for improving inline ECC performance. Each cache line can be allocated to an initiator in the system based on its Route ID. The Route ID allocation to cache line can be done by writing to the EMIF_SSCFG_ECC_RID_INDX_REG and EMIF_SSCFG_ECC_RID_VAL_REG registers. Since the bridge uses unallocated cache lines for all read accesses without Route ID allocation, one or more locations in the cache should be kept unallocated for better performance. To ensure that at least one cache line remains unallocated, in the case all cache lines are allocated by software, the bridge automatically unallocates the 63rd cache line. Write accesses without Route ID allocation result in ECC and data writes to the SDRAM, when the EMIF_SSCFG_ECC_CTRL_REG[4] WR_ALLOC bit is set to 0x0. When EMIF_SSCFG_ECC_CTRL_REG[4] WR_ALLOC is set to 0x1, an unassigned cache-line is allocated to write accesses without Route ID allocation.

9.1.3.4.2 ECC Cache Flush

For low power modes, the bridge supports flushing the cache when DDRSS stop clock request is asserted. When a clock stop is requested, the bridge will start issuing writes to the DRAM until all dirty cache locations are written to the DRAM. Once the writes are complete, the bridge asserts an acknowledge signal to let the subsystem know that the operation is complete. The subsystem uses this acknowledge signal along with acknowledgments from other submodules to generate the final DDRSS stop clock acknowledge to the system.

9.1.3.4.3 ECC Statistics

For 1-bit ECC error, the bridge logs the address location for the error in an internal 2-level deep FIFO. It stores the first two 1-bit ECC errors. The EMIF_SSCFG_ECC_1B_ERR_ADR_LOG_REG register shows the address on top of the internal FIFO. Software should write 0x1 to the EMIF_SSCFG_ECC_1B_ERR_ADR_LOG_REG[29-0] ECC_1B_ERR_ADR field to pop the FIFO and display the next address stored. The FIFO is loaded with the address for the next 1-bit ECC error if it is not full. No address comparison will be performed, that is, if a single address is associated with more than one ECC error, that address is logged twice.

Copyright © 2026 Texas Instruments Incorporated

The number of 1-bit ECC errors can be counted using the EMIF_SSCFG_ECC_1B_ERR_CNT_REG register. The bridge also supports programming a threshold in the EMIF_SSCFG_ECC_1B_ERR_THRSH_REG register. When the 1-bit error count is equal to or greater than the programmed threshold, the bridge sets the EMIF_SSCFG_V2A_INT_RAW_REG[3] ECC1BERR bit and also triggers the DDR0_DDRSS_DRAM_ECC_CORR_ERR_LVL_0 interrupt. When servicing the interrupt, software needs to clear the error count otherwise further interrupts will not be triggered. For 2-bit ECC errors, the bridge sets the EMIF_SSCFG_V2A_INT_RAW_REG[4] ECC2BERR bit and also triggers the DDR0_DDRSS_DRAM_ECC_UNCORR_ERR_LVL_0 interrupt. The bridge does not correct the data for these uncorrectable errors. Along with generating the interrupt, the bridge also reports an error to the requesting initiatior and sends all zeros for the data. The bridge also logs the address location for the error in the EMIF_SSCFG_ECC_2B_ERR_ADR_LOG_REG register.

The bridge sets the EMIF_SSCFG_V2A_INT_RAW_REG[5] ECCM1BERR bit and triggers the DDR0_DDRSS_DRAM_ECC_UNCORR_ERR_LVL_0 interrupt whenever it receives multiple 1-bit errors in different data words of the same SDRAM burst. This is done because the probability of receiving multiple 1-bit errors in different data words of the same SDRAM burst is very low. If this occurs, the chances are that there were multi-bit errors in each data word. Therefore, for reliability, pessimistic approach is taken to report these as a fatal error. The threshold for the number of 1-bit errors that result in an uncorrected error, reporting can be set by writing to the EMIF_SSCFG_ECC_CTRL_REG[11-8] COR_ECC_THRESH field. For reliability, the threshold is always kept at 0/1 meaning 1-bit error in 2 or more data words is reported as a 2-bit error. For debug, the threshold can be changed to a higher value. Note that since these are multiple 1-bit errors, the statistic logging is done in the EMIF_SSCFG_ECC_1B_ERR_CNT_REG and EMIF_SSCFG_ECC_1B_ERR_ADR_LOG_REG registers.

9.1.3.5 Address Alias Prevention

The VBUSM2ZXI bridge checks the VBUSM address received against the valid SDRAM address space programmed in the EMIF_SSCFG_V2A_CTL_REG register. If the VBUSM address for an access falls outside the programmed range the bridge sets to 0x1 the EMIF_SSCFG_V2A_INT_RAW_REG[1] AERR bit and also triggers the DDR0_DDRSS_V2A_OTHER_ERR_LVL_0 interrupt. The address and the Route ID for the command that caused error are logged in the EMIF_SSCFG_V2A_AERR_LOG1_REG and EMIF_SSCFG_V2A_AERR_LOG2_REG registers.

The bridge fragments all incoming transactions into 64-byte accesses aligned at a 64-byte boundary. Therefore, for commands greater than 64 bytes with an address error, each fragment will report an error. This can cause multiple interrupts to be reported if software clears the error interrupt for the first fragment while other fragments are being executed. The address log register will always log the address for the fragment which caused the last interrupt. The valid address range can be programmed using the EMIF_SSCFG_V2A_CTL_REG[9-5] SDRAM_IDX and EMIF_SSCFG_V2A_CTL_REG[4-0] REGION_IDX fields.

Table 9-2 summarizes the scenarios for determining valid address range and interrupt generation.

Table 9-2. REGION_IDX and SDRAM_IDX Scenarios

Condition	Description
REGION_IDX = SDRAM_IDX	DDR region size is equal to the connected SDRAM size. It is the SoC responsibility to ensure that the addresses received by the DDR subsystem do not fall outside the region size. No address error is generated if the address received falls outside the region size.
REGION_IDX < SDRAM_IDX	DDR region size is less than the connected SDRAM size. It is SoC responsibility to ensure that the addresses received by the DDR subsystem do not fall outside the region size. No address error is generated if the address received falls outside the region size.
REGION_IDX > SDRAM_IDX	DDR region size is greater than the connected SDRAM size. Address error is generated if the address received falls outside the connected SDRAM size.

A write access outside the programmed range is discarded. A write error associated status is sent back to the VBUSM interface.

Copyright © 2026 Texas Instruments Incorporated

A read access outside the programmed range is executed on the SDRAM interface as a normal read, but data will contain all zeroes before forwarding it to the VBUSM interface. A read error associated status is sent back to the VBUSM interface along with the read data containing all zeroes.

When inline ECC is enabled, the available SDRAM size is reduced by 1/9th of the size programmed in the SDRAM_IDX field. Therefore, the bridge reports an error if an access falls outside the reduced SDRAM size when inline ECC is enabled. The reduced SDRAM size limit applies to all accesses, both to the protected and non-protected ECC regions.

9.1.3.6 AXI Bus Timeout

The VBUSM2AXI bridge has a timeout counter that expires when no AXI transaction can be sent to the DDR controller or no AXI response is received from the controller for a programmed time interval. The counter only counts when there are pending commands in the bridge and the AXI bus is idle. Therefore, the bridge will not time out during low-power modes. The time interval can be programmed by writing to the EMIF_SSCFG_V2A_BUS_TO[23-0] BUS_TIMER field.

Upon the expiry of the counter, the bridge terminates all pending commands in its internal FIFOs, returns error responses, sets the EMIF_SSCFG_V2A_INT_RAW_REG[2] TOERR bit and triggers the DDR0_DDRSS_V2A_OTHER_ERR_LVL_0 interrupt.

After a timeout occurs, the bridge terminates any new commands received and returns error response. Writing a value of 0x0 to the EMIF_SSCFG_V2A_BUS_TO[23-0] BUS_TIMER field exits the timeout mode. The other method to exit the timeout mode is to reset the DDRSS0, thus resetting the VBUSM2ZXI bridge, the DDR controller, and the DDR PHY.

9.1.3.7 Leaky Bucket Function

The VBUSM2AXI bridge implements a leaky bucket mechanism at each LPT-HPT arbitration point. This will prevent LPT commands from getting stuck in the pipe forever due to overload of HPT commands.

A programmable system threshold will be used to trigger leaky bucket. This can be programmed in the EMIF_SSCFG_V2A_LEAKY_THRESH_REG. The threshold determines how many HPT commands can be sent in a row before a single LPT command is forwarded.

9.1.3.8 Drain Function

The VBUSM2AXI bridge implements a mechanism to drain the DDR controller. The drain action will temporarily pause the submission of commands to the controller until the read command(s) that triggered the drain operation have been resolved.

Each read going to the DDR controller will have an associated internal counter that starts at zero. This counter will increment for each write or read command given to the controller after that particular read is sent. If any read command counter exceeds the programmed threshold the bridge will start a drain action. The threshold can be programmed in EMIF_SSCFG_V2A_DRAIN_THRESH_REG.

9.1.3.9 DDRSS Interrupts

The VBUSM2AXI bridge sets to 0x1 the EMIF_SSCFG_V2A_INT_RAW_REG[1] AERR bit, if the VBUSM address for an access that falls outside the DDR space programmed in the EMIF_SSCFG_V2A_CTL_REG register.

The VBUSM2AXI bridge sets to 0x1 the EMIF_SSCFG_V2A_INT_RAW_REG[2] TOERR bit, if it detects a hang on its interface to the DDR controller.

The VBUSM2AXI bridge sets to 0x1 the EMIF_SSCFG_V2A_INT_RAW_REG[3] ECC1BERR bit, if the threshold for 1-bit ECC errors is met.

The VBUSM2AXI bridge sets to 0x1 the EMIF_SSCFG_V2A_INT_RAW_REG[4] ECC2BERR bit, in case of 2-bit errors for a read access performed within the SDRAM address range protected by ECC.

Copyright © 2026 Texas Instruments Incorporated

The DDRSS0 asserts particular interrupt line only if the interrupts are enabled by writing 0x1 to the corresponding bit in the EMIF_SSCFG_V2A_INT_SET_REG register. The interrupts can be disabled by writing 0x1 to the corresponding bit in the EMIF_SSCFG_V2A_INT_CLR_REG register.

When interrupts are enabled, the corresponding bits in the EMIF_SSCFG_V2A_INT_STAT_REG register are also set if an interrupt condition occurs. The interrupts can be cleared once serviced by writing 0x1 to the corresponding bit in the EMIF_SSCFG_V2A_INT_STAT_REG register as well as writing to the EMIF_SSCFG_V2A_EOI_REG register. The subsystem will send an interrupt pulse, if there are any bits set in the Interrupt Status register (EMIF_SSCFG_V2A_INT_STAT_REG) when the End of Interrupt register (EMIF_SSCFG_V2A_EOI_REG) is written.

VBUSM2AXI Bridge Events shows the events that are generated by the VBUSM2AXI bridge.

Table 9-3. VBUSM2AXI Bridge Events

Event Flag	Event Mask	Description
EMIF_SSCFG_V2A_INT_RAW_REG[4] ECC2BERR EMIF_SSCFG_V2A_INT_STAT_REG[4] ECC2BERR	EMIF_SSCFG_V2A_INT_SET_REG[4] ECC2BERR_EN EMIF_SSCFG_V2A_INT_CLR_REG[4] ECC2BERR_EN	Generated in case of 2-bit errors for a read access within the ECC protected SDRAM address range. For more information, see Section 9.1.3.4.3.
EMIF_SSCFG_V2A_INT_RAW_REG[3] ECC1BERR EMIF_SSCFG_V2A_INT_STAT_REG[3] ECC1BERR	EMIF_SSCFG_V2A_INT_SET_REG[3] ECC1BERR_EN EMIF_SSCFG_V2A_INT_CLR_REG[3] ECC1BERR_EN	Generated in case of meeting the threshold for 1-bit ECC errors. For more information, see Section 9.1.3.4.3.
EMIF_SSCFG_V2A_INT_RAW_REG[2] TOERR EMIF_SSCFG_V2A_INT_STAT_REG[2] TOERR	EMIF_SSCFG_V2A_INT_SET_REG[2] TOERR_EN EMIF_SSCFG_V2A_INT_CLR_REG[2] TOERR_EN	Generated in case of a hang of the interface between the bridge and the DDR controller. For more information, see Section 9.1.3.6.
EMIF_SSCFG_V2A_INT_RAW_REG[1] AERR EMIF_SSCFG_V2A_INT_STAT_REG[1] AERR	EMIF_SSCFG_V2A_INT_SET_REG[1] AERR_EN EMIF_SSCFG_V2A_INT_CLR_REG[1] AERR_EN	Generated if the VBUSM address for an access falls outside the programmed range. For more information, see Section 9.1.3.5.

9.1.3.10 DDRSS Memory Regions

Table 9-4 shows all memory regions associated with the DDRSS0.

Table 9-4. DDRSS0 Memory Regions

Region	Start Address	End Address	Region Size
DDRSS0 wrapper logic registers	0x00F300000	0x00F3001FF	512 B
DDR controller registers	0x00F308000	0x00F309FFF	8 KB
DDR PHY independent module registers	0x00F30A000	0x00F30BFFF	8 KB
DDR PHY registers	0x00F30C000	0x00F30FFFF	16 KB
External SDRAM data space	0x080000000	0x0FFFFFFFF	2 GB
	0x880000000	0xFFFFFFFFF	30 GB

9.1.3.11 DDRSS Dynamic Frequency Change Interface

This interface is used for handshaking between DDRSS0 and CTRL_MMR0 to dynamically change DDR clock frequency to support LPDDR4 Frequency Set Point (FSP). The frequency change can be initiated either by a SoC processor or by the DDRSS0.

The associated CTRL_MMR0 registers for processor initiated frequency change are:

- CTRLMMR_CHNG_DDR4_FSP_REQ

Copyright © 2026 Texas Instruments Incorporated

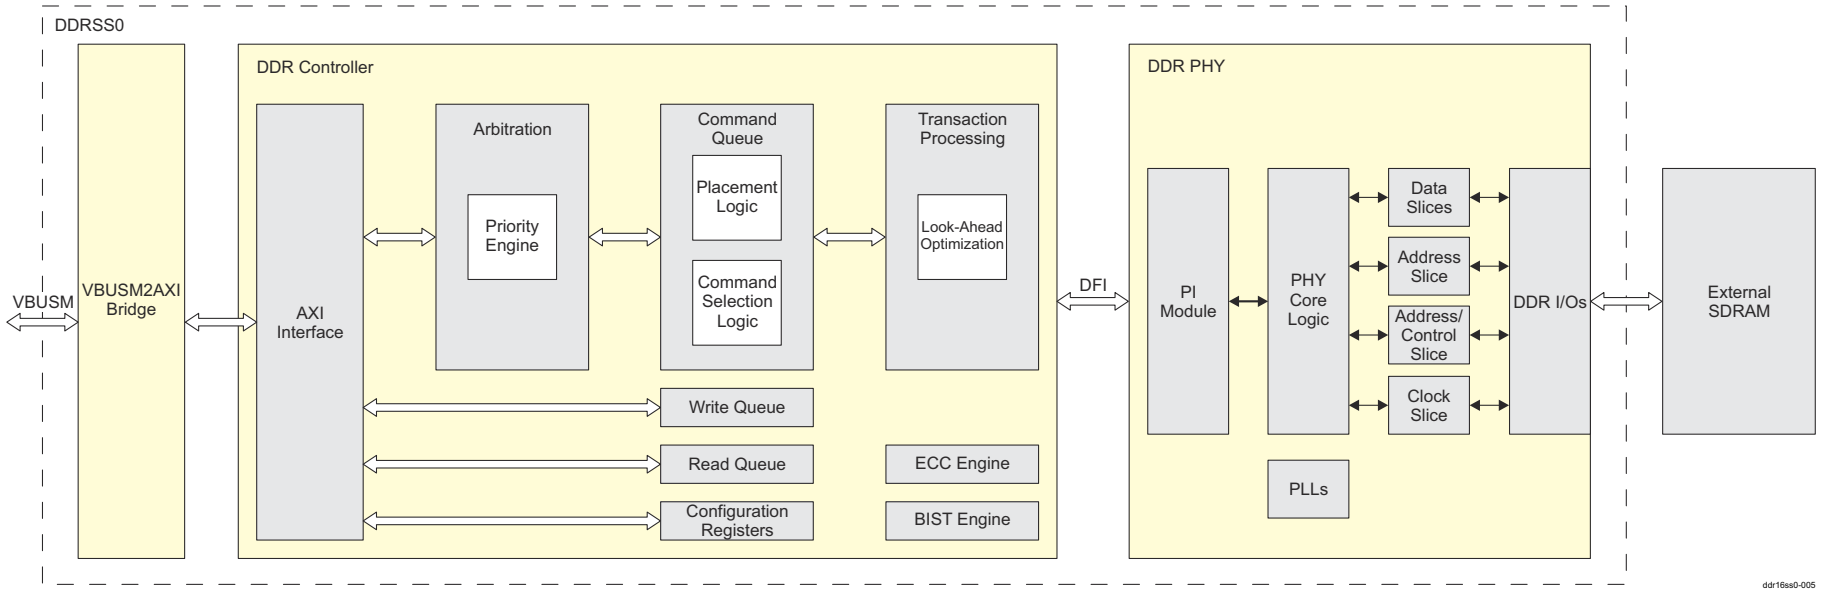
- CTRLMMR_CHNG_DDR4_FSP_ACK

The associated CTRL_MMR0 registers for DDRSS0 initiated frequency change are:

- CTRLMMR_DDR4_FSP_CLKCHNG_REQ
- CTRLMMR_DDR4_FSP_CLKCHNG_ACK

The sequence for an SoC processor initiated frequency change is as follows:

1. The processor writes the desired frequency to the CTRLMMR_CHNG_DDR4_FSP_REQ[1-0] REQ_TYPE field.
2. The processor sets to 0x1 the CTRLMMR_CHNG_DDR4_FSP_REQ[8] REQ bit to initiate frequency change.
3. The processor programs PLL12 according to the CTRLMMR_CHNG_DDR4_FSP_REQ[1-0] REQ_TYPE value.
4. The processor polls the CTRLMMR_CHNG_DDR4_FSP_ACK[7] ACK and CTRLMMR_CHNG_DDR4_FSP_ACK[0] ERROR bits to check if the frequency change has been completed successfully.



The sequence for DDRSS0 initiated frequency change is as follows:

1. DDRSS0 requests frequency change by asserting the CTRLMMR_DDR4_FSP_CLKCHNG_REQ[7] REQ bit and the CTRLMMR_DDR4_FSP_CLKCHNG_REQ[1-0] REQ_TYPE field. The REQ bit is also connected to the DDR0_DDRSS_PLL_FREQ_CHANGE_REQ_0 interrupt.
2. Software reads the CTRLMMR_DDR4_FSP_CLKCHNG_REQ[1-0] REQ_TYPE value and programs PLL12 accordingly.
3. After the DDRSS0_FCLK has been changed software should set to 0x1 the CTRLMMR_DDR4_FSP_CLKCHNG_ACK[0] ACK bit.

9.1.3.12.1 DDR PHY Interface (DFI)

The DDR controller and DDR PHY are connected via DDR PHY Interface (DFI) which is used for transferring control information and data between the PHY and the controller. For more information about DFI, see http://www.ddr-phy.org/.

Copyright © 2026 Texas Instruments Incorporated

9.1.3.12.2 Command Queue

The DDR controller contains a command queue which uses a placement algorithm to determine the order of commands to be placed into the command queue. The placement logic follows many rules to determine where new commands should be inserted into the queue, relative to the contents of the command queue at a time. Placement is determined by considering address collisions, source collisions, data collisions, command types and priorities. The placement logic also attempts to maximize efficiency of the DDR controller through command grouping and bank splitting.

9.1.3.12.2.1 Placement Logic

The placement logic is a 2-stage queue which determines the order of commands that run in the DDR controller. The placement logic follows rules for determining placement of new commands into the queue, relative to the contents of the command queue at that time. Placement is determined by considering coherency, address collisions, source collisions, data collisions, user assigned priority, latency, age, and command type to offer low latency for critical controllers while optimizing bandwidth for all controllers. A second reordering stage allows ready-to-run commands to start even if the head-of-queue command is not yet ready to run. In addition, the queue can be disabled completely, resulting in an in-line queue that services requests in the order that they arrive.

The DDR controller also has a full look-ahead facility that reduces the effect of page misses by pre-conditioning rows for upcoming requests by using “spare” cycles in preceding transactions.

9.1.3.12.2.2 Command Selection Logic

After a command is in the command queue, command selection logic determines the method of pulling commands from the queue for running. On each clock cycle, the selection logic scans the entries of the command queue for determining the command to run. Commands for running are based on bank readiness, availability of at least 1 burst of data (writes), availability of storage for at least 1 burst of data (reads), bus turnaround timing, and conflicts. Similar to the placement rules, a command does not run before a command that was placed ahead of it in the command queue if it conflicts with address, source ID, or bank commands. Lower priority commands can run ahead of higher priority commands if the higher priority commands are not ready to run, as long as they do not conflict with commands that are ahead in the command queue.

9.1.3.12.3 Transaction Processing

The transaction command processing logic is used to process the commands in the command queue. The logic organizes the commands to the memories in such a way that data throughput is maximized. Bank opening and closing cycles are used for data transfers. The logic reviews the entire command queue for look-ahead of which banks have to be accessed in the future and ensures that the programed memory timing conditions are met. This flexibility allows the controller to be tuned to extract the maximum performance out of memories. During processing, the controller examines the commands and issues the appropriate set of signals to the memory.

9.1.3.12.4 Paging Policy

The DDR controller offers a flexible paging policy that allows open page operation, closed page operation, or an auto-precharge-per-command option that allows both modes simultaneously. Auto-precharge-per-command allows marking a particular controller or transaction (for example, a CPU cache) as a closed-page transaction. This type of transaction reduces power and improves latency for the next transaction to a different row in the same SDRAM bank. Other transactions can be marked as open page transactions. This type of transaction reduces power and improves latency and bandwidth to the next transaction to the same row in the same SDRAM bank.

9.1.3.12.5 DDR Controller Initialization

Once the power to the SDRAM and SoC is stable, the DDR controller must be initialized. It then automatically initializes the external memory. Please refer to the Processor SDK for the software drivers to initalize the DDR registers and memory

10.1 Interrupt Architecture

J722S Interrupt Architecture includes information on how to utilize various interrupts and events in the system and relationships between interrupts and events.

An interrupt is defined as a physical signal which can be routed to the interrupt controller of various processors, which can cause the Interrupt Service Routine (ISR). This physical signal can be either a pulse or level and the polarity can be either negative or positive. And an interrupt is correspondent to an individual wire.

An event is defined as information transported by the event bus or PSI_L bus. Events are coded using an event index. The same event bus or PSI_L bus is used to transport multiple events. An event can also be routed and multiplexed to different locations. Events can't trigger a processor's ISR directly. They must go through the Interrupt Aggregator (IA) to convert the event into an interrupt line. For more information, see , *Interrupt Aggregator (INTAGGR)*

The DMA transfer using BCDMA and PktDMA in J722S can only be triggered using an event. The SoC level interrupt could be used as a BCDMA trigger using L2G logic. Interrupts in the SoC level can't be used to trigger a pktDMA transfer.

Each type of processor has its unique interrupt controller. All A53 cores share a single Generic Interrupt Controller (GIC). Each R5 micro controller has its own dedicated interrupt controller, called Vectored Interrupt Manager (VIM). Please refer to Section 10.2 for the detailed usage.

J722S also contains multiple SoC level interrupt routers. The main function of those SoC level interrupt routers is to provide flexibility to select interrupt sources from a large group of interrupt sources. Many places use this feature, such as GPIO interrupts and some time synchronization related interrupts.

J722S contains two ESM modules. ESM is used to consolidate/monitor the error events in the device. In this document, ESM may also be referred to as ESM0.

J722S also has some chip level glue logic to convert some miscellaneous signals used as interrupt sources. Those miscellaneous signals are normally self-clear signals and do not need to clear after the Interrupt Service Routine (ISR) like the normal interrupts generated by the peripherals.

Figure 10-1 shows the high level interrupt architecture in J722S.

Copyright © 2026 Texas Instruments Incorporated

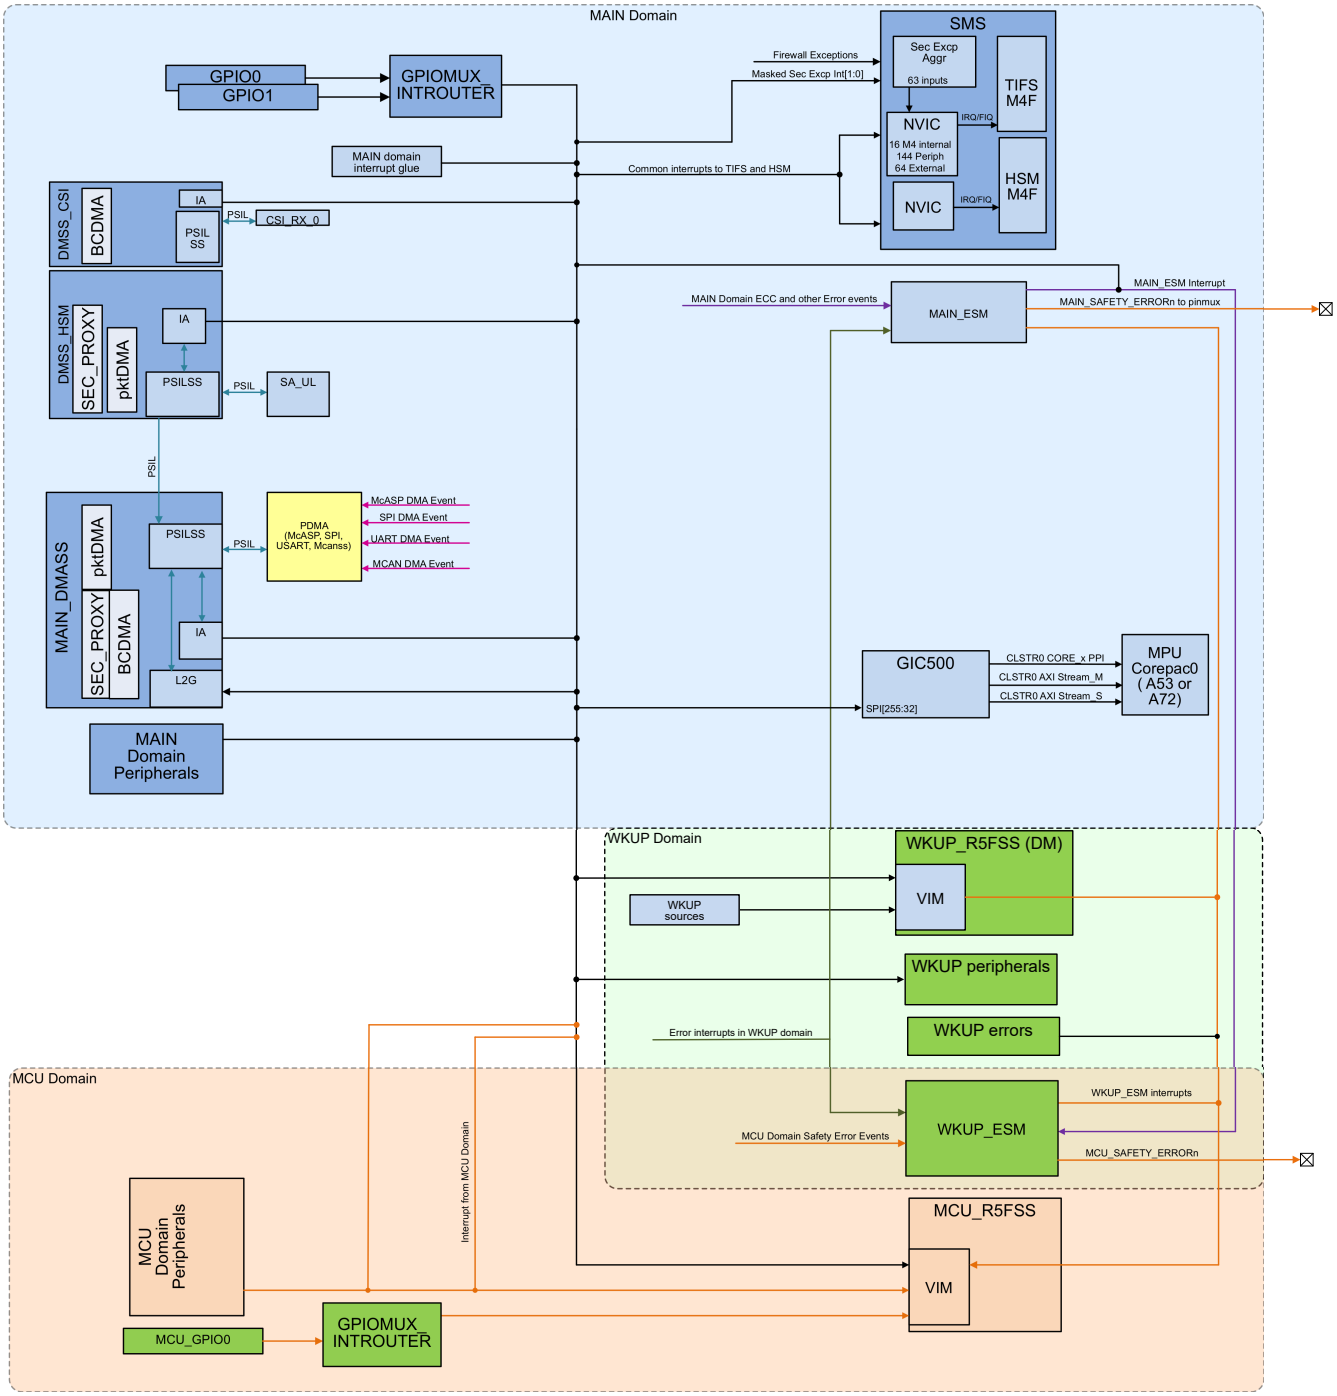

Figure 10-1. J722S Interrupt Architecture

10.1.1 ESM Connectivity

J722S contains two ESM modules to consolidate the error interrupts in SoC. One is in the MAIN domain and one is in the WKUP domain. Figure 10-2 shows how error interrupts are connected to these two ESM. See also *Interrupts (Inputs)* and *Interrupts (Outputs)*.

Copyright © 2026 Texas Instruments Incorporated

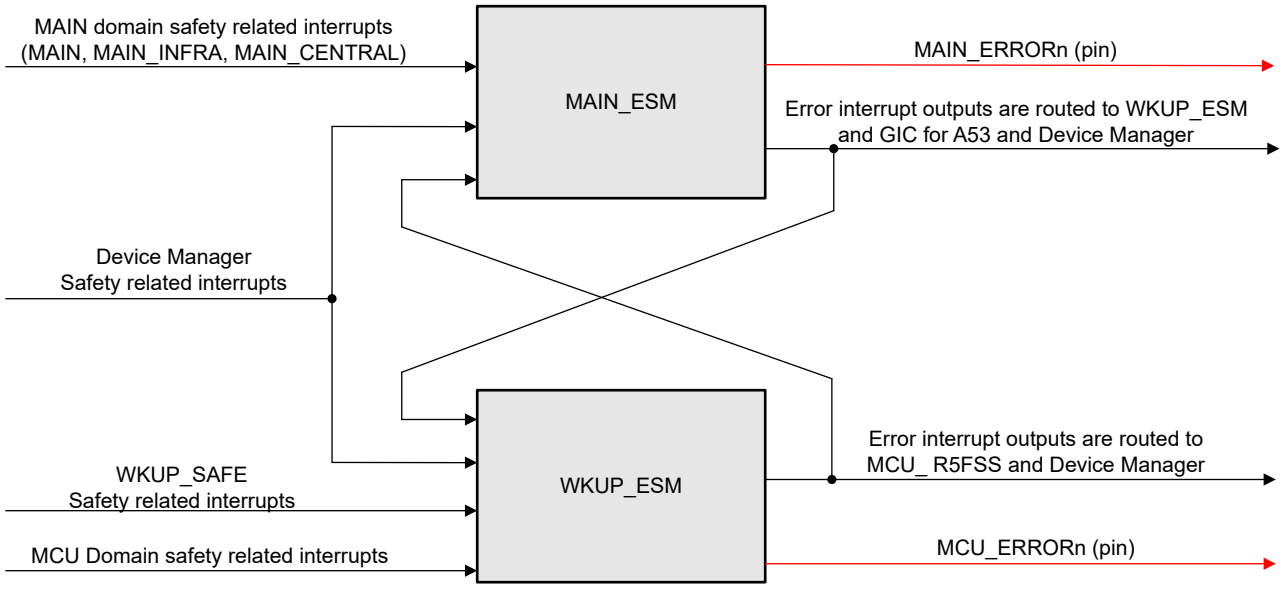

Figure 10-2. ESM Connections

The error interrupts from the WKUP_R5FSS domain are routed to both MAIN_ESM and WKUP_ESM. Users can configure ESM to cause ESM generating interrupt output from the interrupt inputs. The interrupt outputs of the MAIN_ESM are routed as interrupt inputs to the WKUP_ESM. The interrupt outputs of the WKUP_ESM are routed as the interrupt inputs to the MAIN_ESM. This means that user can configure the device to use one ESM to monitor the error interrupts for the whole device. J722S supports the following three use cases.

10.1.1.1 Using WKUP_ESM to Monitor All Error Events in SoC

In this use case, the MAIN_ESM is used to consolidate all the error interrupts in the MAIN domain and the WKUP_R5FSS domain as MAIN_ESM's interrupt outputs, which are routed as interrupt inputs to the WKUP_ESM.

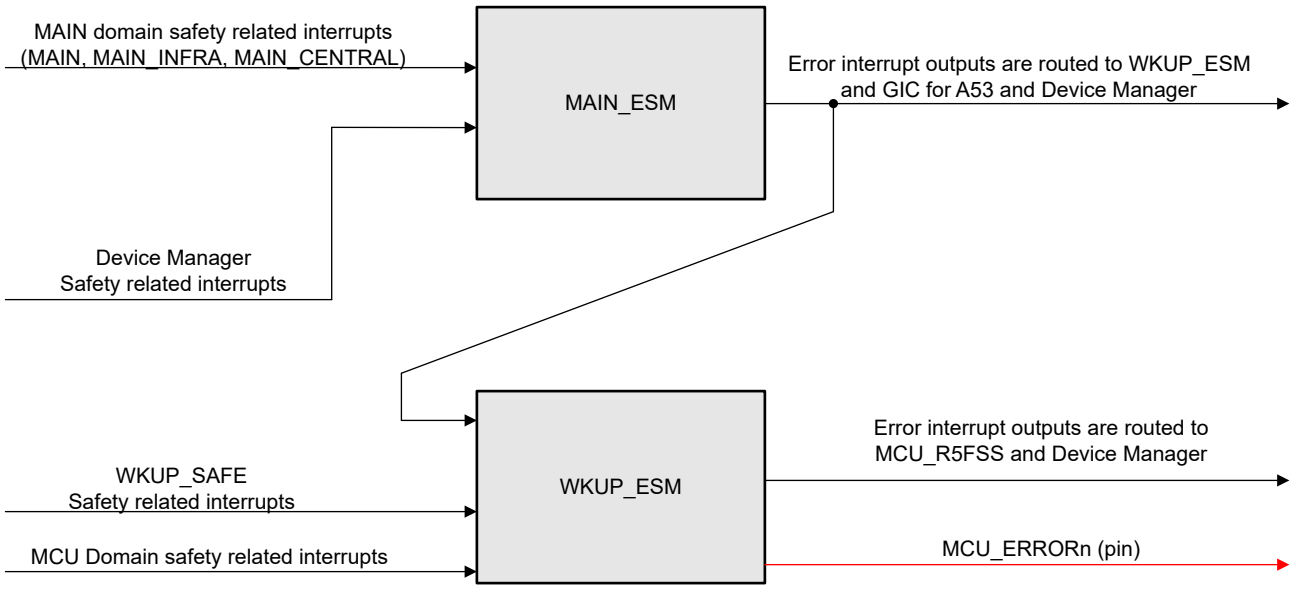

Figure 10-3. Using WKUP_ESM for All Error Interrupts in SoC

Copyright © 2026 Texas Instruments Incorporated

In this use case, the MAIN_ESM should be configured to disable the interrupt inputs coming from the WKUP_ESM interrupts. If those interrupt inputs are not disabled by the MAIN_ESM, the dependence loop will be formed as following:

1. Error interrupts in the MAIN domain are routed to MAIN_ESM trigger interrupt outputs generated by the MAIN_ESM
2. The error interrupt outputs from the MAIN_ESM are routed to the WKUP_ESM as interrupt inputs
3. Those error interrupt inputs trigger the WKUP_ESM generating its error interrupts outputs
4. Those interrupt outputs from the WKUP_ESM are routed back to the MAIN_ESM as interrupt inputs. If those interrupts are not disabled at the MAIN_ESM, they trigger MAIN_ESM generating interrupt outputs in the MAIN_ESM again. Going back to step 1 again.

In addition, since WKUP_R5FSS error events are already routed to the MAIN_ESM, so the input events in the WKUP_ESM connecting to those error events from the WKUP_R5FSS domain shall be disabled, otherwise those events can trigger the interrupt in both the MAIN_ESM as well as the WKUP_ESM

10.1.1.2 Using MAIN_ESM to Monitor All Error Interrupts in SoC

In this configuration, the WKUP_ESM is used to consolidate all the error interrupts from the WKUP domain and the WKUP_safe domain as interrupt outputs, and those interrupt outputs from the WKUP_ESM are routed as interrupt inputs to the MAIN_ESM. In order to avoid the interrupt dependence loop, the WKUP_ESM shall disable the interrupt inputs from ESM0.

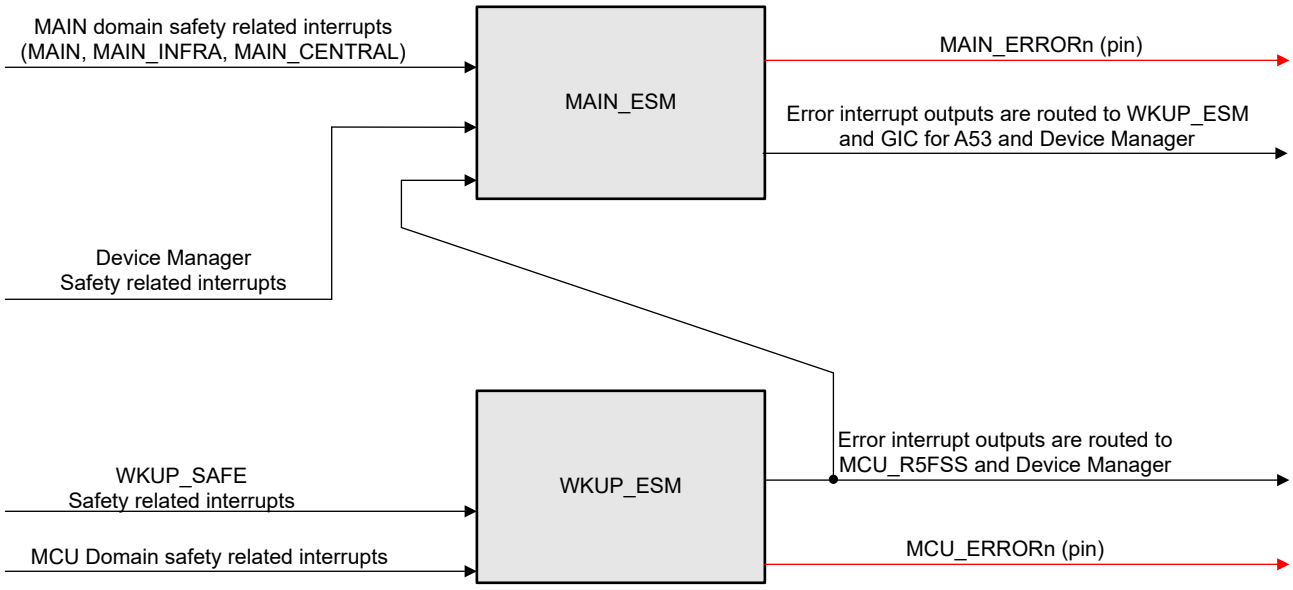

Figure 10-4. Using MAIN_ESM to Monitor All Error Interrupts in SoC

10.1.1.3 ESM Configuration During Deep Sleep Mode

When device is in deep sleep mode, only the components in the WKUP_R5FSS domain and the WKUP_SAFE are available. The MAIN domain is powered off, so the MAIN_ESM is no longer available. Since WKUP_ESM is located in the WKUP_SAFE domain, the WKUP_ESM is monitoring all of the error events during the deep sleep mode and informs the device manager.

Copyright © 2026 Texas Instruments Incorporated

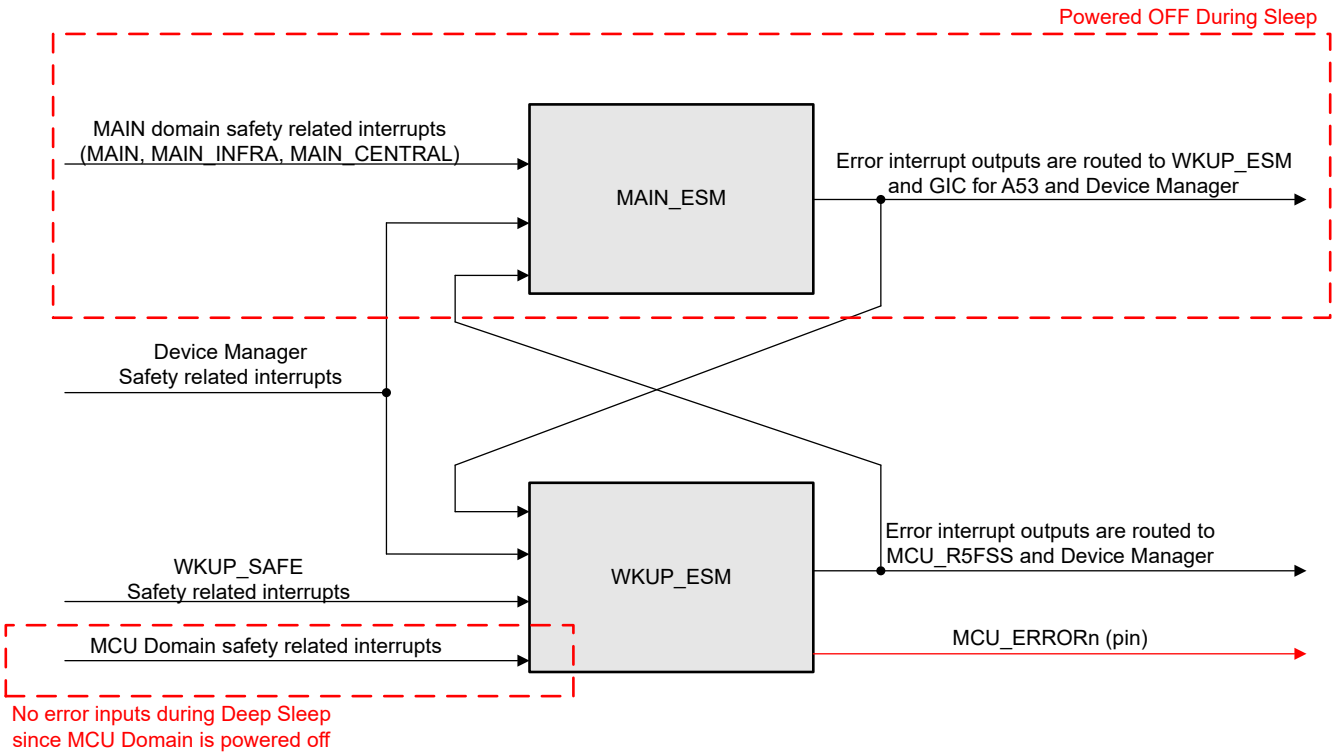

Figure 10-5. Deep Sleep Use Case

10.1.2 PSIL Events

PSIL Events are mainly generated by the BCDMA and the pktDMA. In addition, the SEC_PROXY IPC module also generates event outputs. PSIL Events can be directly utilized by the BCDMA and the pktDMA. If those events need to be processed by processor, the events need to be converted to interrupts through the Interrupt Aggregator (IA) Module. Refer to , *Interrupt Aggregator (INTAGGR)* for information on how IA is used. Figure 10-6 shows which modules generates events and how the events are converted to the interrupt.

BCDMA transfer can only be triggered through an event or by software. There are 32 SoC level interrupt signals that can be used to trigger a BCDMA transfer.

10.1.3 Object Missing

This object is not available in the repository.

10.1.4 Utilizing Miscellaneous Signals as Interrupt

Some of the signals are aggregated through glue logic and need to be handled separately.

10.1.4.1 Aggregated Interrupt from Timeout Gasket

There are multiple timeout gaskets in SoC, some of them are inserted at the initiator side and the others are inserted at the target interface side. Each timeout gasket module generates its own interrupt. Instead of routing the interrupt from each timeout gasket individually to the processor, the interrupts from all the timeout gasket inserted at the target sides are aggregated together (ORed), and all the interrupts from all the timeout gasket inserted at the initiator sides are aggregated together (ORed). The status of each interrupt status is captured by the TOG_STAT registers in both WKUP_CTRL_MMR and MCU_CTRL_MMR. Refer to Figure 10-7.

Copyright © 2026 Texas Instruments Incorporated

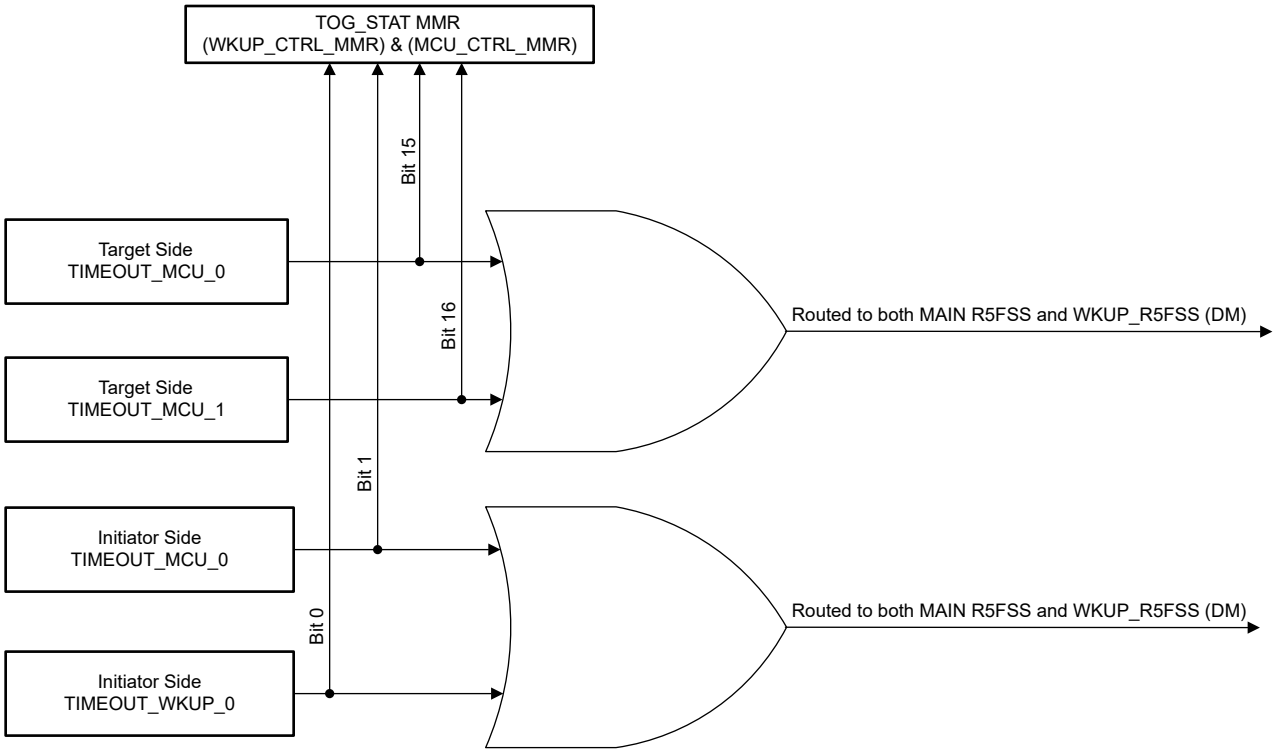

Figure 10-7. Interrupt from Timeout Gaskets

10.1.4.2 Aggregated DCC Interrupt

There are multiple DCC modules in the main domain and each DCC module generates its own DCC_done interrupt. The DCC_done interrupt from all the DCC modules in the main domain are aggregated (ORed) together before it is routed to all the processors, refer to Figure 10-8.

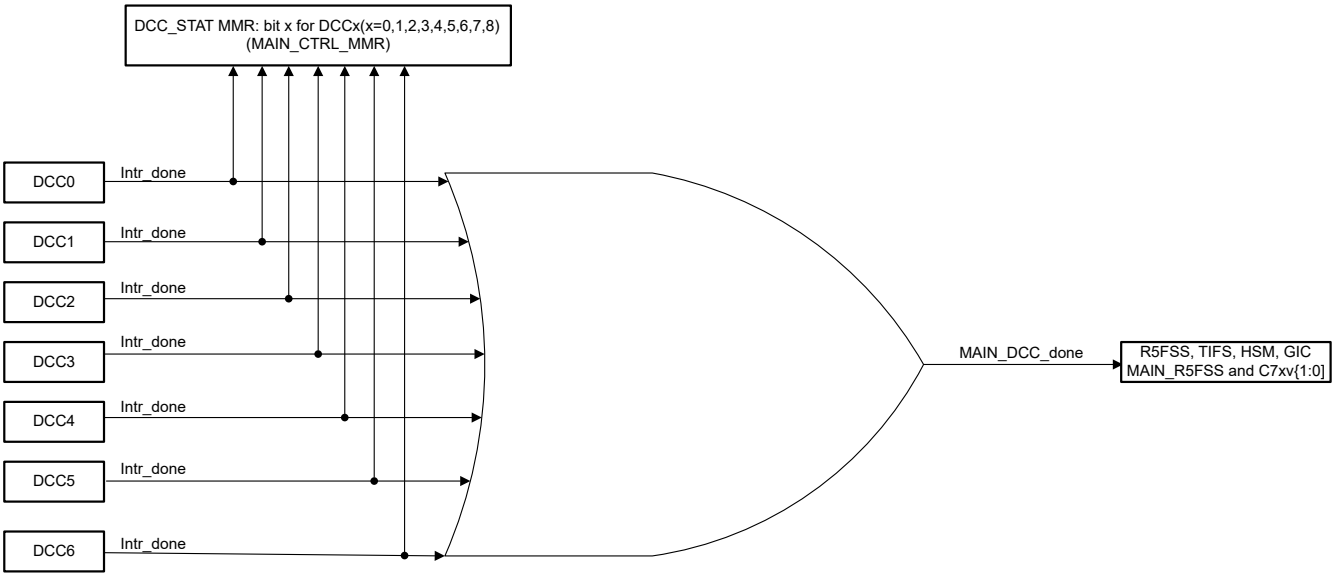

Figure 10-8. DCC Intr_done Interrupt Aggregation

Copyright © 2026 Texas Instruments Incorporated

10.1.4.3 Aggregated Access Error Interrupt from CBASS

CBASS modules are the interconnection blocks on the SoC level to provide access path between initiators and targets. When the transaction is not completed successfully, an interrupt is generated by the CBASS and the error transaction is logged by the CBASS module.

There are multiple CBASS modules on the SoC level to provide three layers of interconnect: the data plane, security configuration plane and debug configuration plane. The CBASS access error from the security configuration plane is only routed to TIFS and HSM, and the other CBASS access errors are aggregated before routing it to the processors, refer to Figure 10-9.

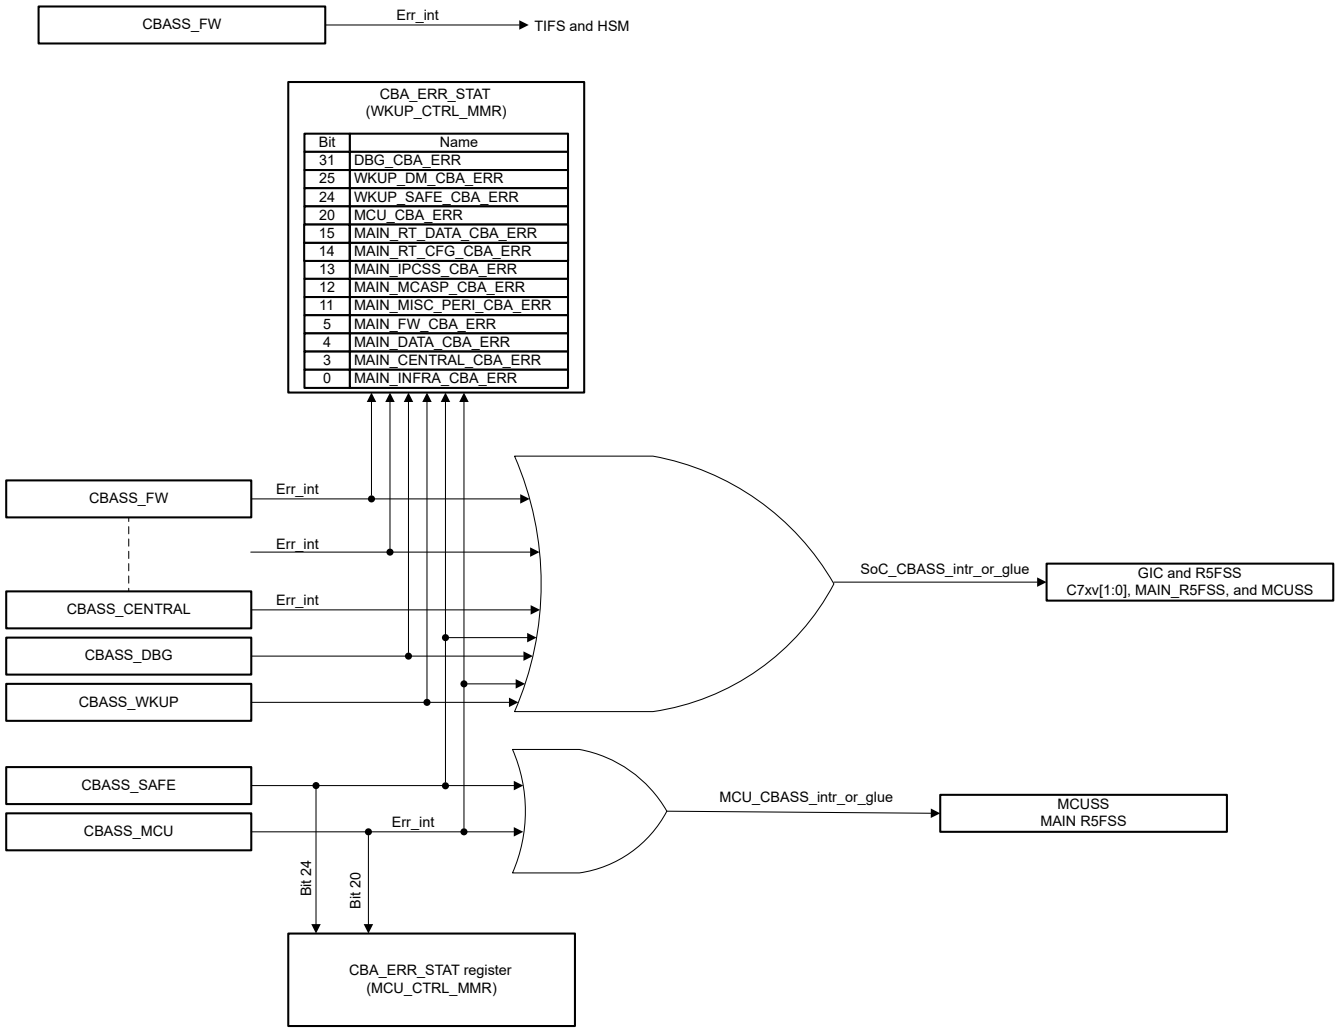

Figure 10-9. Aggregated CBASS Access Error

10.1.4.4 Access Error to Control Register Block Interrupt Aggregation

There are multiple register blocks on the SoC level, and each register block generates an error interrupt when there is an access error. Those access error interrupts are aggregated together before they are routed to processor, refer to Figure 10-10.

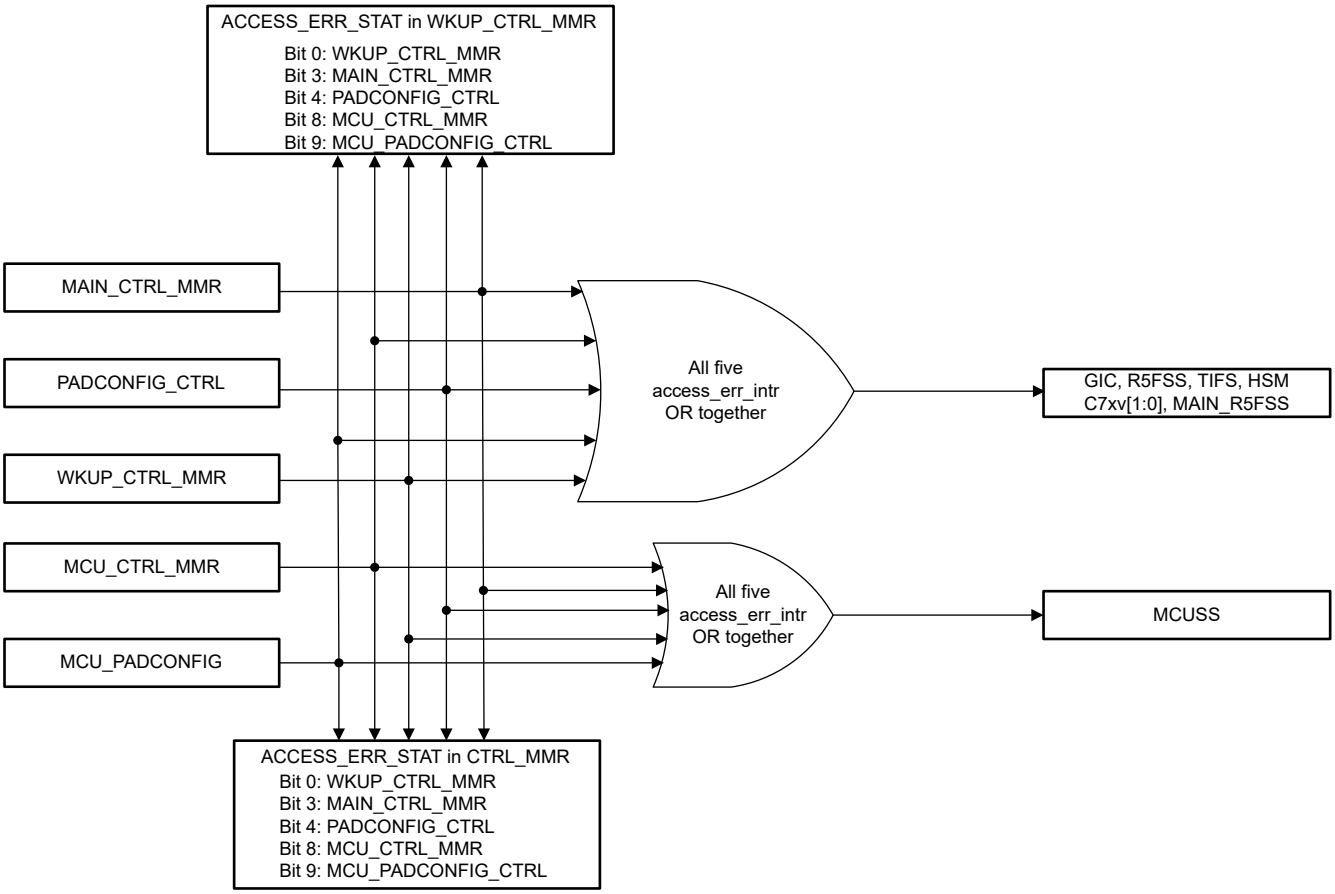

Figure 10-10. Access Error Aggregation

10.2 Interrupt Controllers

10.2.1 Generic Interrupt Controller (GICSS)

This section describes the Generic Interrupt Controller (GICSS) module in the device.

10.2.1.1 GICSS Overview

The device GICSS is a TI module that is based on the Arm GIC-500 interrupt controller. The Arm GIC-500 is a high-performance, area-optimized, built-time configurable interrupt controller which detects, manages, and distributes system interrupts to the Arm Cortex-A53 processors in the Compute Cluster.

The Arm GIC-500 is compliant to the Arm GICv3 standard. It only supports cores (such as A53) that implement the Armv8 architecture and the GIC CPU interface with the standard GIC Stream Protocol Interface. The GICSS includes additional logic (TI wrapper) to fully integrate the Arm GIC-500 into the SoC.

10.2.1.1.1 GICSS Features

Note

This chapter provides only a brief description of the GICSS functionality and features. For more details on this module, refer to the *Arm®CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

The Arm GIC-500 supports the following features in the device:

- Module revision: r1p1
- Supports both cores in the dual-A53 MPU cluster

Copyright © 2026 Texas Instruments Incorporated

- 16 software generated interrupts (SGIs) per core
- 16 private peripheral interrupts (PPIs) per core
- 256 shared peripheral interrupts (SPIs)
- Locality-specific peripheral interrupts (LPIs), used for message-based interrupts
- Interrupt translation service (ITS)
  - Device isolation
  - ID translation for message-based interrupts
  - This allows virtual machines to program devices directly
- Interrupt masking and prioritization
- Programmable, affinity-based interrupt routing
- 32 priorities for each interrupt
- Three different interrupt groups
  - Group 0
  - Non-secure group 1
  - Secure group 1

Additionally, the GICSS wrapper logic provides the following features:

- Synchronizes interrupt inputs to GICSS clock
- Implements AXI2VBUSM and VBUSM2AXI bridges
  - Used for bus protocol conversion (AXI-to-VBUSM and VBUSM-to-AXI, respectively)
- Implements an integrated ECC aggregator
  - Only used to inject errors (for testing purposes)

Note

Some features may not be available. See *Module Integration* for more information.

10.2.1.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

10.2.1.3 GICSS Functional Description

Note

This chapter provides only a brief description of the GICSS functionality and features. For more details on this module, refer to the *Arm®CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

10.2.1.3.1 GICSS Block Diagram

Figure 10-11 shows the GICSS block diagram.

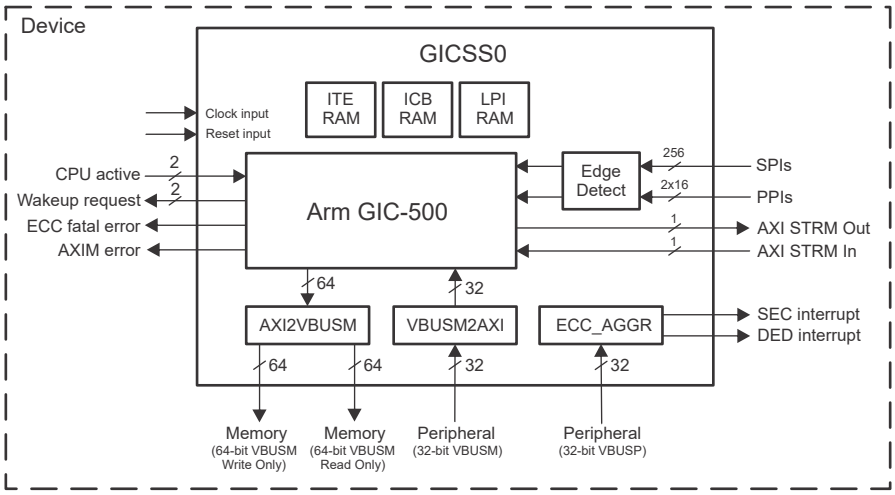

Figure 10-11. GICSS Block Diagram

10.2.1.3.2 Arm GIC-500

The Arm GIC-500 is responsible for detecting, managing and communicating system interrupts to the dual-core A53 cluster. The main difference between the Arm GIC-500 and previous Arm GIC versions is the direct communication with the CPU(s). Previously, an interrupt controller would set a pending bit to a CPU and that CPU would then have to query an interrupt controller MMR to find out what to do. Now, the Arm GIC-500 sends interrupts to a CPU via a dedicated message interface and the CPU communicates back about interrupts through the same interface. The CPU now uses writes and reads to system registers instead of over the memory interface. This leads to reduced latency and the ability to route interrupts to different CPUs based on a set of rules.

The Arm GIC-500 is divided into three main sections:

- **Distributor**: The Distributor receives interrupts from the wire interrupts and the programming interface. It is responsible for prioritizing these interrupts and sending them to the CPU interface via the GIC Stream Protocol Interface.
- **Redistributor**: There is one Redistributor per core. Each Redistributor holds the state that is individual to a particular core (such as the settings for PPIs and SGIs). It also stores the LPIs for that core after they have been generated using the ITS.
- **ITS**: The ITS is responsible for translating message-based interrupts from device peripherals into LPIs. The user can also use the ITS to manage existing LPIs. Note that the ITS is not used for other types of interrupt

10.2.1.3.3 GICSS Interrupt Types

The GICSS supports four types of interrupts:

- *Software Generated Interrupts (SGIs)*: There are 16 SGIs (ID0-ID15). These are inter-processor interrupts. SGIs can be sent using either Arm system registers or by writing to the Software Generated Interrupt Register (GICD_SGIR).

Copyright © 2026 Texas Instruments Incorporated

- *Private Peripheral Interrupts (PPIs)*: There are 16 PPIs (ID16-ID31). These are wired interrupts dedicated to a specific CPU. Many are reserved to specific functions via convention. These can be either active-low levels (by default), or rising edge triggered (software programmable).
- *Shared Peripheral Interrupts (SPIs)*: There are 256 SPIs (ID32-ID288). These are wired interrupts that can be routed to any core or cluster, based on the programming of that interrupt in the GICSS. These are active-high levels (by default), or rising edge triggered (software programmable).
- *Locality-Specific Peripheral Interrupts (LPIs)*: There are 57,344 of these. These interrupts are used for message-based interrupts from a peripheral. They are generated through writes to the GICSS peripheral interface. The information associated with these is located in memory. The GICSS keeps a small 64-entries cache on-board in order to reduce latency either for specific interrupts or for most-recently-used. LPIs can be routed to different CPUs based on programmed rules.

10.2.1.3.4 GICSS Interfaces

The GICSS has the following main interfaces:

- A pair of 64-bit VBUSM write-only and read-only controller interfaces
  - AXI2VBUSM bridge converts the standard 64-bit AXI4 controller interface into this pair of interfaces
  - The AXI4 controller interface allows the GICSS ITS and redistributors to access main memory
- 32-bit VBUSM peripheral interface
  - Provides access to Arm GIC-500 internal resources
  - Handles all message-based interrupts. Message-based interrupts can generate SPIs or LPIs, depending on the register that is written
  - VBUSM2AXI bridge converts this interface into an 32-bit AXI4 peripheral interface
- 32-bit VBUSP peripheral interface
  - Provides access to internal ECC aggregator
- Physical interrupt and power signals
  - Inputs: CPU active signals, SPIs and PPIs (can be programmed as either level-sensitive, or edge-triggered)
  - Outputs: Error signals and wake-up requests
- GIC Stream Protocol Interface
  - Consists of a pair of AXI4-Stream interfaces (one upstream and one downstream 16-bit AXI4-Stream interface) that the GICSS uses to send interrupts to the core and receive notifications when the core activates interrupts
  - There is a pair of physical interfaces, one in each direction, for each cluster

10.2.1.3.5 GICSS Interrupt Outputs

Table 10-2 lists the interrupts that are generated by the GICSS.

Table 10-2. GICSS Interrupt Outputs

Interrupt Name	Description
GICSS0_AXIM_ERR_0	GICSS bus error interrupt. This interrupt is triggered if the GICSS receives an error on a bus transaction, such as a decode or protection error. This is a pulse-high interrupt. If this interrupt occurs, the GICSS might lose interrupts and must be reset. If it is not reset, behavior becomes unpredictable.
GICSS0_ECC_FATAL_0	GICSS uncorrectable ECC error interrupt. Indicates an uncorrectable 2-bit error detected in one of the ITS cache memories. This is a pulse-high interrupt. If this interrupt occurs, the GICSS might lose interrupts and must be reset. If it is not reset, behavior becomes unpredictable.
GICSS0_ECC_AGGR_CORR_LEVEL_0	GICSS ECC aggregator correctable (SEC) error interrupt
GICSS0_ECC_AGGR_UNCORR_LEVEL_0	GICSS ECC aggregator uncorrectable (DED) error interrupt
GICSS0_GIC_PWR0_WAKE_REQUEST_0	GICSS wake requests for A53 cores. Asserted state indicates that an interrupt is pending for a processor that has set the PROCESSORSLEEP bit in the GICR_WAKER register. This bit indicates that the SoC should wake up the indicated CPU so that it can process the interrupt.
GICSS0_GIC_PWR0_WAKE_REQUEST_1

10.2.1.3.6 GICSS ECC Support

The Arm GIC-500 has built-in SECDED ECC on its memories to protect against errors. The syndrome generation and checking is done internally.

Additionally, the GICSS wrapper integrates an ECC aggregator (GICSS0_ECC_AGGR) in order to allow errors to be injected for testing purposes. The generic ECC aggregator functionality is described in *ECC Aggregator*. Note that the GICSS0_ECC_AGGR supports only a subset of this functionality.

Table 10-3 shows the memory ID for each ECC endpoint. The corresponding memory ID needs to be written in the GICSS0_ECC_AGGR_VECTOR[10-0] ECC_VECTOR bit field for proper operation.

Table 10-3. GICSS0_ECC_AGGR Memory ID Mapping

ECC Aggregator	Memory ID	ECC Endpoint
GICSS0_ECC_AGGR	0	ICB RAM
	1	ITE RAM
	2	LPI RAM
	3	VBUSM2AXI bridge
	4	AXI2VBUSM read bridge
	5	AXI2VBUSM write bridge

10.2.1.3.7 GICSS AXI2VBUSM and VBUSM2AXI Bridges

The GICSS uses the AXI4 controller interface to allow the ITS and redistributors to access main memory. It is expected that the main memory (attached to a CBASS VBUSM port) holds the following:

- ITS translation tables
- ITS command queue, which is written by software in order to program the ITS
- LPI configuration table, which holds the priorities and enable bits for LPIs
- LPI pending tables, which can hold information on whether each LPI is pending on each core

The AXI2VBUSM bridge converts the standard 64-bit AXI4 controller interface into a pair of 64-bit VBUSM write-only and read-only controller interfaces. AXI4 has a separate command channel for read and write, and the AXI2VBUSM bridge keeps them separate, so that the system may prioritize or arbitrate the traffic between them as appropriate.

The GICSS uses the AXI4 peripheral interface to provide access to the programming interfaces of all its parts (distributor, redistributors, ITS). The VBUSM2AXI bridge converts the standard 32-bit VBUSM controller interface into an 32-bit AXI4 peripheral interface.

Note

The AXI2VBUSM and VBUSM2AXI bridges do not implement any MMRs.

10.3 Interrupt Router (INTROUTER)

10.3.1 INTROUTER Integration

See the Interrupts section of the Module Integration Chapter for details on clocks, resets and hardware requests.

Table 10-5. Interrupts (Outputs) (continued)

Instance	Interrupt Output Line	Destination Interrupt
PSRAMECC0	PSRAMECC0_ECC_CORR_LEVEL_OUT_0	ESM0_ESM_LVL_EVENT_IN_29
	PSRAMECC0_ECC_UNCORR_LEVEL_OUT_0	ESM0_ESM_LVL_EVENT_IN_90
PSRAMECC1	PSRAMECC1_ECC_CORR_LEVEL_OUT_0	ESM0_ESM_LVL_EVENT_IN_108
	PSRAMECC1_ECC_UNCORR_LEVEL_OUT_0	ESM0_ESM_LVL_EVENT_IN_109
WKUP_PSRAMECC_8K0	WKUP_PSRAMECC_8K0_ECC_CORR_LEVEL_OUT_0	WKUP_ESM0_ESM_LVL_EVENT_IN_42
	WKUP_PSRAMECC_8K0_ECC_CORR_LEVEL_OUT_0	ESM0_ESM_LVL_EVENT_IN_8
	WKUP_PSRAMECC_8K0_ECC_UNCORR_LEVEL_OUT_0	WKUP_ESM0_ESM_LVL_EVENT_IN_43
	WKUP_PSRAMECC_8K0_ECC_UNCORR_LEVEL_OUT_0	ESM0_ESM_LVL_EVENT_IN_13
R5FSS0_CORE0	R5FSS0_CORE0_CTI_OUT_0	R5FSS0_CORE0_INTR_IN_175
	R5FSS0_CORE0_ECC_CORRECTED_LEVEL_OUT_0	ESM0_ESM_LVL_EVENT_IN_208
	R5FSS0_CORE0_ECC_UNCORRECTED_LEVEL_OUT_0	ESM0_ESM_LVL_EVENT_IN_209
	R5FSS0_CORE0_EXP_INTR_OUT_0	ESM0_ESM_LVL_EVENT_IN_210
	R5FSS0_CORE0_EXP_INTR_OUT_0	R5FSS0_CORE0_INTR_IN_4
	R5FSS0_CORE0_PMU_OUT_0	R5FSS0_CORE0_INTR_IN_94
	R5FSS0_CORE0_VALFIQ_OUT_0	R5FSS0_CORE0_INTR_IN_95
	R5FSS0_CORE0_VALIRQ_OUT_0	R5FSS0_CORE0_INTR_IN_96
R5FSS0_COMMON0	R5FSS0_COMMON0_COMMRX_LEVEL_0_OUT_0	R5FSS0_CORE0_INTR_IN_90
	R5FSS0_COMMON0_COMMTX_LEVEL_0_OUT_0	R5FSS0_CORE0_INTR_IN_91
	R5FSS0_COMMON0_ECC_DE_TO_ESM_0_OUT_0	ESM0_ESM_LVL_EVENT_IN_211
	R5FSS0_COMMON0_ECC_SE_TO_ESM_0_OUT_0	ESM0_ESM_LVL_EVENT_IN_212
WKUP_R5FSS0_CORE0	WKUP_R5FSS0_CORE0_CTI_OUT_0	WKUP_R5FSS0_CORE0_INTR_IN_175
	WKUP_R5FSS0_CORE0_ECC_CORRECTED_LEVEL_OUT_0	ESM0_ESM_LVL_EVENT_IN_30
	WKUP_R5FSS0_CORE0_ECC_UNCORRECTED_LEVEL_OUT_0	ESM0_ESM_LVL_EVENT_IN_91
	WKUP_R5FSS0_CORE0_EXP_INTR_OUT_0	ESM0_ESM_LVL_EVENT_IN_124
	WKUP_R5FSS0_CORE0_EXP_INTR_OUT_0	WKUP_R5FSS0_CORE0_INTR_IN_4
	WKUP_R5FSS0_CORE0_PMU_OUT_0	WKUP_R5FSS0_CORE0_INTR_IN_58
	WKUP_R5FSS0_CORE0_VALFIQ_OUT_0	WKUP_R5FSS0_CORE0_INTR_IN_59
	WKUP_R5FSS0_CORE0_VALIRQ_OUT_0	WKUP_R5FSS0_CORE0_INTR_IN_60
WKUP_R5FSS0_COMMON0	WKUP_R5FSS0_COMMON0_COMMRX_LEVEL_0_OUT_0	WKUP_R5FSS0_CORE0_INTR_IN_5
