

# TPS1HTC30-Q1, 30mΩ, 6A Single-Channel Automotive Smart High-Side Switch

## 1 Features

- Single-channel smart high-side power switch for 24V and 48V automotive systems with full diagnostics
- **TPS1HTC30-Q1**: Operating voltage range: 6V to 60V, Overvoltage protection: 66V
- **TPS1HTC30C-Q1**: Operating voltage range: 6V to 70V, meets **ISO 21780** standard requirements
- Low R<sub>ON</sub>: 30mΩ typical, 55mΩ maximum
- Low standby current: < 0.5μA
- Low quiescent current (I<sub>q</sub>): < 2mA
- Improve system level reliability through [adjustable current limiting](#)
  - Current limit: 2A –16A
- Accurate current sensing: ±4% at 1A
- Protection
  - Overload and short-circuit protection
  - Integrated inductive discharge clamp
  - Undervoltage lockout (UVLO) protection
  - Loss of GND, loss of supply protection
  - Reverse battery protection with external components
- Diagnostics
  - On and off state output open-load and short-to-battery detection
  - Overload and short to ground detection
  - Absolute and relative thermal shutdown detection
- [Functional Safety-Capable](#)
  - [Documentation available to aid functional safety system design](#)
- Operating junction temperature: –40 to 125°C
- Input control: 1.8V, 3.3V and 5V logic compatible
- Integrated fault sense voltage scaling for ADC protection
- Qualifications
  - AEC-Q100 qualified for automotive applications
    - Temperature grade 1: –40°C to +125°C, T<sub>A</sub>
- 14-pin thermally-enhanced TSSOP package

## 2 Applications

- General [resistive, inductive, and capacitive loads](#)

## 3 Description

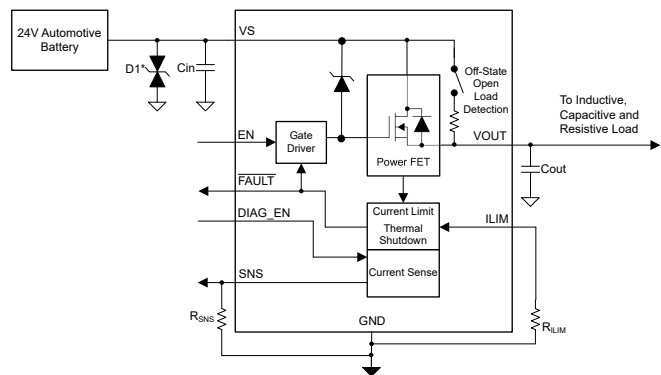

TPS1HTC30-Q1 is a single-channel, smart high-side switch, with integrated NMOS power FET and charge pump, designed to meet the requirements of 24V and 48V automotive battery systems. The low R<sub>ON</sub> minimizes device power dissipation driving load current up to 6A DC, and the 60V DC operating range improves system robustness. The TPS1HTC30C-Q1 supports a maximum voltage rating of 70V DC.

The device integrates protection features such as thermal shutdown, output clamp, and current limit to improve system robustness during faults such as short circuit. The device implements an adjustable current limit to improve the reliability of the system by reducing inrush current when driving capacitive loads. The device also provides an accurate current sense that allows for improved load diagnostics such as overload and open-load detection, enabling better predictive maintenance. The device is available in a small 14-pin leaded package with 0.65mm pitch, minimizing the PCB footprint.

### Package Information

PART NUMBER	PACKAGE <sup>(1)</sup>	PACKAGE SIZE <sup>(2)</sup>	BODY SIZE (NOM)
TPS1HTC30-Q1	PWP (HTSSOP, 14)	6.50mm × 5.00mm	4.40mm × 5.00mm

- (1) See the orderable addendum at the end of the datasheet.
- (2) The package size (length × width) is a nominal value and includes pins, where applicable.

## 5 Pin Configuration and Functions

Figure 5-1. PWP Package, 14-Pin HTSSOP Top View

Table 5-1. Pin Functions

over operating free-air temperature range (unless otherwise noted)

PIN		TYPE <sup>(1)</sup>	DESCRIPTION
NAME	NO		
DIAG_EN	3	I	Enable/disable pin for diagnostics, internal pulldown (Active high signal)
EN	2	I	Enables/disables channel output current, internal pullup. EN = 1: ON or EN = 0: OFF (Active high signal)
FAULT	4	O	Open drain fault output. Referred to as FAULT, FLT, or fault pin. (Active low signal)
GND	1	Power	Ground of device. Connect to resistor- diode ground network to have reverse supply/battery protection
ILIM	7	O	Adjustable current limit. Short to ground or leave floating for internal fixed current limit.
NC	11	N/A	No internal connection. Leave floating
OL_ON / LATCH	5	I	OL_ON: Enable/disable pin for open load detection in the ON state. (Active high signal) Latch: Sets retry behavior. LATCH =0: auto-retry after faults or LATCH =1: latch off after faults, internal pulldown.
Pad	Thermal Pad	--	Thermal Pad, internally shorted to ground. Tie to IC ground externally.
SNS	6	O	Analog current output proportional to load current - Connect a resistor to GND to convert to voltage.
VOUT	8, 9, 10	Power	Output of high side switch, connected to load
VS	12, 13, 14	Power	Power supply Input

(1) I = input, O = output

### 5.1 Recommended Connections for Unused Pins

The device is designed to provide an enhanced set of diagnostic and protection features. However, if the system design only allows for a limited number of I/O connections, some pins can be considered as optional.

Table 5-2. Connections for Optional Pins

PIN NAME	CONNECTION IF NOT USED	IMPACT IF NOT USED
SNS	Ground through 1k $\Omega$ resistor	Analog sense is not available.
LATCH	Float or ground through R <sub>PROT</sub> resistor	With LATCH unused, the device performs an auto-retry after a fault. If latched behavior is desired, but the system describes limited I/O, it is possible to use one microcontroller output to control the latch function of several high-side channels.
ILIM	Float	If the ILIM pin is left floating, the device is set to the default internal current-limit threshold. This is considered a fault state for the device.
FAULT	Float	If the FAULT pin is unused, the system cannot read faults from the output.

**Table 5-2. Connections for Optional Pins (continued)**

PIN NAME	CONNECTION IF NOT USED	IMPACT IF NOT USED
DIAG_EN	Float or ground through R <sub>PROT</sub> resistor	With DIAG_EN unused, the analog sense, open-load, and short-to-battery diagnostics are not available.

- (1) Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If used outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.
- (2) For further details, see the section regarding switch-off of an inductive load.

### 6.2 ESD Ratings

			VALUE	UNIT
$V_{ESD}$	Electrostatic discharge	Human body model (HBM), per AEC Q100-002 Classification Level H2 <sup>(1)</sup>	All pins except VS and VOUT	±2000 V
		Human body model (HBM), per AEC Q100-002 Classification Level H3A <sup>(1)</sup>	VS and VOUT with respect to GND	±4000 V
		Charged device model (CDM), per AEC Q100-011 Classification Level C5	All pins	±750 V

- (1) AEC-Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specifications

## 8 Detailed Description

### 8.1 Overview

The TPS1HTC30-Q1 is a automotive, single-channel, fully-protected, high-side power switch with an integrated NMOS power FET and charge pump rated for 60V DC operation. The TPS1HTC30-Q1 can support a maximum voltage of 64V, while the TPS1HTC30C-Q1 can support up to 70V. Full diagnostics and high-accuracy current-sense features enable intelligent control of the load. Low logic high threshold,  $V_{IH}$ , of 1.5V on the input pins allow use of MCUs down to 1.8V. A programmable current-limit function greatly improves the reliability of the whole system. The device diagnostic reporting has two pins to support both digital status and analog current-sense output, for multiplexing the MCU analog or digital interface among devices.

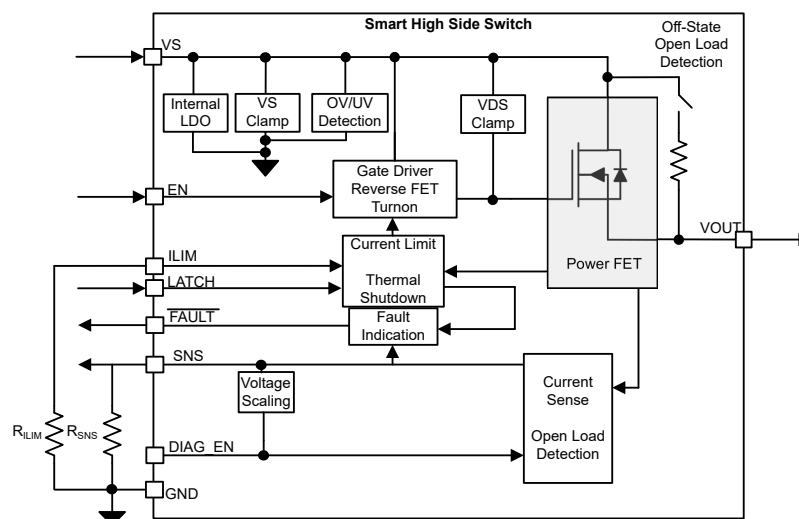

The digital status report is implemented with an open-drain structure on the fault pin. When a fault condition occurs, the pin is pulled down to GND. An external pullup is required to match the microcontroller supply level. High-accuracy current sensing allows a better real-time monitoring effect and more-accurate diagnostics without further calibration. A current mirror is used to source  $1 / K_{SNS}$  of the load current, which is reflected as voltage on the SNS pin.  $K_{SNS}$  is a constant value across temperature and supply voltage. The SNS pin can also report a fault by forcing a voltage of  $V_{SNSFH}$  that scales with the diagnostic enable voltage so that the max voltage seen by the system ADC is within an acceptable value. This removes the need for an external Zener diode or resistor divider on the SNS pin.

The external high-accuracy current limit allows setting the current limit value by application. The external high-accuracy current limit highly improves the reliability of the system by clamping the inrush current effectively under start-up or short-circuit conditions. Also, the external high-accuracy current limit can save system costs by reducing PCB trace, connector size, and the preceding power-stage capacity. An internal current limit can also be implemented in this device. The lower value of the external or internal current-limit value is applied.

An active drain to source voltage clamp is built in to address switching off the energy of inductive loads, such as relays, solenoids, pumps, motors, and so forth. During the inductive switching-off cycle, both the energy of the power supply ( $E_{BAT}$ ) and the load ( $E_{LOAD}$ ) are dissipated on the high-side power switch itself. With the benefits of process technology and excellent IC layout, the TPS1HTC30-Q1 device can achieve excellent energy dissipation capacity, which can help save the need of using external free-wheeling circuitry in most cases.

The TPS1HTC30-Q1 device can be used as a high-side power switch for a wide variety of resistive, inductive, and capacitive loads, including the low-wattage bulbs, LEDs, relays, solenoids, and heaters.

### 8.2 Functional Block Diagram

## 8.3 Feature Description

### 8.3.1 Accurate Current Sense

The high-accuracy current-sense function is internally implemented, which allows real-time monitoring and more-accurate diagnostics without further calibration. A current mirror is used to source  $1 / K_{SNS}$  of the load current, flowing out to the external resistor between the SNS pin and GND, and reflected as voltage on the SNS pin.

$K_{SNS}$  is the ratio of the output current and the sense current. The accuracy values of  $K_{SNS}$  quoted in the electrical characteristics do take into consideration temperature and supply voltage. Each device is internally calibrated while in production, so post-calibration by users is not required in most cases.

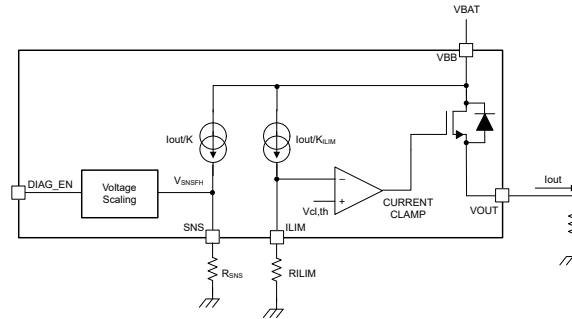

The maximum voltage out on the SNS pin is clamped to  $V_{SNSFH}$ , which is the fault voltage level. To make sure that this voltage is not higher than the system can tolerate, TI has correlated the voltage coming in on the DIAG\_EN pin with the maximum voltage out on the SNS pin. If DIAG\_EN is between  $V_{IH}$  and 3.3V, the maximum output on the SNS pin is approximately 3.3V. However, if the voltage at DIAG\_EN is above 3.3V, then the fault SNS voltage,  $V_{SNSFH}$ , tracks that voltage up to 5V. Tracking is done because the GPIO voltage output that is powering the diagnostics through DIAG\_EN is close to the maximum acceptable ADC voltage within the same microcontroller. Therefore, the sense resistor value,  $R_{SNS}$ , can be selected to maximize the range of currents needed to be measured by the system. The  $R_{SNS}$  value must be selected based on application need. The minimum usable  $R_{SNS}$  value is bounded by the ADC minimum acceptable voltage,  $V_{ADC,min}$ , for the smallest load current needed to be measured by the system,  $I_{LOAD,min}$ . The maximum acceptable  $R_{SNS}$  value has to ensure the  $V_{SNS}$  voltage is below the  $V_{SNSFH}$  value so that the system can determine faults. This difference between the maximum readable current through the SNS pin,  $I_{LOAD,max} \times R_{SNS}$ , and the  $V_{SNSFH}$  is called the headroom voltage,  $V_{HR}$ . The headroom voltage is determined by the system but is important so that there is a difference between the maximum readable current and a fault condition. Therefore, the maximum  $R_{SNS}$  value has to be the  $V_{SNSFH}$  minus the  $V_{HR}$  times the sense current ratio,  $K_{SNS}$  divided by the maximum load current the system must measure,  $I_{LOAD,max}$ . Use the following equation to see the boundary equation.

$$V_{ADC,min} \times K_{SNS} \div I_{LOAD,min} \leq R_{SNS} \leq (V_{SNSFH} - V_{HR}) \times K_{SNS} \div I_{LOAD,max} \quad (1)$$

**Figure 8-1. Voltage Indication on the Current-Sense Pin**

The maximum current the system wants to read,  $I_{LOAD,max}$ , must be below the current-limit threshold because after the current-limit threshold is tripped the  $V_{SNS}$  value goes to  $V_{SNSFH}$ . Additionally, currents being measured can be up to the maximum ILIM value but the current sense output accuracy is not specified above the maximum rated value in the Current Sense Characteristics.

**Figure 8-2. Current-Sense and Current-Limit Block Diagram**

Because this scheme adapts based on the voltage coming in from the MCU, there is no need to have a Zener diode on the SNS pin to protect from high voltages.

### 8.3.2 Programmable Current Limit

A high-accuracy current limit allows higher reliability, which protects the power supply during short circuit or power up. Also, a high-accuracy current limit can save system costs by reducing PCB traces, connector size, and the capacity of the preceding power stage.

Current limit offers protection from over-stressing to the load and integrated power FET. Current limit holds the current at the set value, and pulls up the SNS pin to  $V_{SNSFH}$  and asserts the FAULT pin as diagnostic reports. The device can be configured to any one of the three current-limit thresholds explained below, based on  $I_{LIM}$  pin connection. The typical deglitch time for the current limit to assert is 2.5 $\mu$ s.

- External programmable current limit: An external resistor,  $R_{ILIM}$  is used to set the channel current limit. When the current through the device exceeds  $I_{LIM}$  (current limit threshold), a closed loop steps in immediately.  $V_{GS}$  voltage regulates accordingly, leading to the  $V_{DS}$  voltage regulation. When the closed loop is set up, the current is clamped at the set value. The external programmable current limit provides the capability to set the current-limit value by application. It is recommended to set  $R_{ILIM}$  from 10k $\Omega$  to 50k $\Omega$ , to achieve  $K_{CL}$  tolerance as specified in [Section 6.5](#).

Additionally this value can be dynamically changed by changing the resistance on the ILIM pin. This can be seen in the [Applications Section](#).

- Internal current limit: When  $I_{LIM}$  pin is shorted to ground, the device current limit is internally fixed to 16A. To use the device for large-current applications, tie the  $I_{LIM}$  pin directly to the device GND.
- Internal current limit: When  $I_{LIM}$  pin open, the device current limit is internally fixed to 8A. This level is still above the nominal operation for the device to operate in DC steady state but is low enough that if a pin fault occurs and the  $R_{ILIM}$  opens up, the current does not default to the highest rating and put additional stress on the power supply.

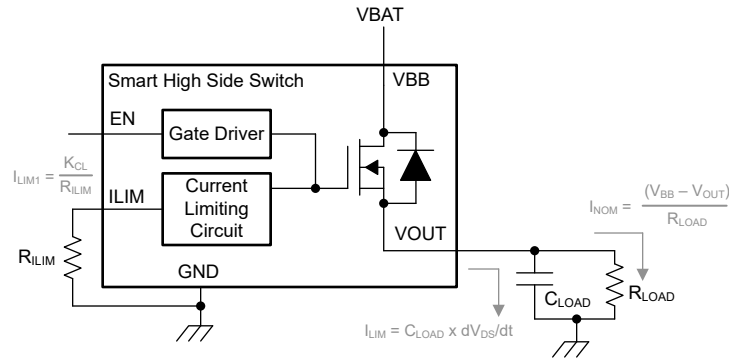

Note that if a GND network is used (which leads to the level shift between the device GND and board GND), the ILIM pin must be connected with device GND. Calculate  $R_{ILIM}$  with [Equation 2](#).

$$R_{ILIM} = \frac{K_{CL}}{I_{LIM}} \quad (2)$$

For better protection from a hard short-to-GND condition (when  $V_S$  and input are high and a short to GND happens suddenly), an open-loop fast-response behavior is set to turn off the channel, before the current-limit closed loop is set up. With this fast response, the device can achieve better inrush-suppression performance. For more information about this current limiting feature, see [Section 8.3.5.1](#).

#### 8.3.2.1 Capacitive Charging

[Figure 8-3](#) shows the typical set up for a capacitive load application and the internal blocks that function when the device is used. Note that all capacitive loads have an associated "load" in parallel with the capacitor that is described as a resistive load but in reality it can be inductive or resistive.

**Figure 8-3. Capacitive Charging Circuit**

The first thing to check is that the nominal DC current,  $I_{NOM}$ , is acceptable for the TPS1HTC30-Q1 device. This can easily be done by taking the  $R_{\theta JA}$  from the [Thermal Information](#) and multiplying the  $R_{ON}$  of the TPS1HTC30-Q1 and the  $I_{NOM}$  with it, add the ambient temperature and if that value is below the thermal shutdown value, then the device can operate with that load current. For an example of this calculation see the [Section 9.2](#).

The second key care about for this application is to make sure that the capacitive load can be charged up completely without the device hitting thermal shutdown. This is because if the device hits thermal shutdown during the charging, the resistive nature of the load in parallel with the capacitor starts to discharge the capacitor over the duration the TPS1HTC30-Q1 is off. Note that there are some applications with high enough load impedance that the TPS1HTC30-Q1 hitting thermal shutdown and trying again is acceptable; however, for the majority of applications the system must be designed so that the TPS1HTC30-Q1 does not hit thermal shutdown while charging the capacitor.

With the current clamping feature of the TPS1HTC30-Q1, capacitors can be charged up at a lower inrush current than other high current limit switches. This lower inrush current means that the capacitor takes a little longer to charge all the way up.

For more information about capacitive charging with high side switches, see the [How to Drive Resistive, Inductive, Capacitive, and Lighting Loads](#) application note. This application note has information about the thermal modeling available along with quick ways to estimate if a high side switch is able to charge a capacitor to a given voltage.

### 8.3.3 Inductive-Load Switching-Off Clamp

When an inductive load is switching off, the output voltage is pulled down to negative, due to the inductance characteristics. The power FET can break down if the voltage is not clamped during the current decay period. To protect the power FET in this situation, an internal drain to gate clamp, namely the  $V_{DS,clamp}$  is used to clamp the voltage between the drain and source of the device.

$$V_{DS,clamp} = V_{BAT} - V_{OUT} \quad (3)$$

During the current-decay period ( $T_{DECAY}$ ), the power FET is turned on for inductive energy dissipation. Both the energy of the power supply ( $E_{BAT}$ ) and the load ( $E_{LOAD}$ ) are dissipated on the high-side power switch itself, which is called  $E_{HSD}$ . If resistance is in series with inductance, some of the load energy is dissipated in the resistance.

$$E_{HSD} = E_{BAT} + E_{LOAD} = E_{BAT} + E_L - E_R \quad (4)$$

From the high-side power switch view,  $E_{HSD}$  equals the integration value during the current decay period.

$$E_{HSD} = \int_0^{T_{DECAY}} V_{DS,clamp} \times I_{OUT}(t) dt \quad (5)$$

$$T_{\text{DECAY}} = \frac{L}{R} \times \ln \left[ \frac{R \times I_{\text{OUT(MAX)}} + |V_{\text{OUT}}|}{|V_{\text{OUT}}|} \right] \tag{6}$$

$$E_{\text{HSD}} = L \times \frac{V_{\text{BAT}} \times |V_{\text{OUT}}|}{R^2} \times \left( R \times I_{\text{OUT(MAX)}} - |V_{\text{OUT}}| \ln \left[ \frac{R \times I_{\text{OUT(MAX)}} + |V_{\text{OUT}}|}{|V_{\text{OUT}}|} \right] \right) \tag{7}$$

When R approximately equals 0, E<sub>HSD</sub> can be given simply as:

$$E_{\text{HSD}} = \frac{1}{2} \times L \times I_{\text{OUT(MAX)}}^2 \frac{V_{\text{BAT}} \times |V_{\text{OUT}}|}{R^2} \tag{8}$$

**Figure 8-4. Driving Inductive Load**

**Figure 8-5. Inductive-Load Switching-Off Diagram**

As discussed previously, when switching off, battery energy and load energy are dissipated on the high-side power switch, which leads to the large thermal variation. For each high-side power switch, the upper limit of the maximum safe power dissipation depends on the device intrinsic capacity, ambient temperature, and board dissipation condition.

### 8.3.4 Inductive Load Demagnetization

When switching off an inductive load, the inductor can impose a negative voltage on the output of the switch. The device includes voltage clamps between VS and VOUT to limit the voltage across the FETs and demagnetize load inductance if there is any. The negative voltage applied at the OUT pin drives the discharge of inductor current. [Figure 8-6](#) shows the device discharging a 400mH load.

Figure 8-6. TPS1HTC30 Inductive Discharge (400mH)

The maximum acceptable load inductance is a function of the energy dissipated in the device and therefore the load current and the inductive load. The maximum energy and the load inductance the device can withstand for one pulse inductive dissipation at 125°C is shown in Figure 8-7. The device can withstand 40% of this energy for one million inductive repetitive pulses with a >4Hz repetitive pulse. If the application parameters exceed this device limit, use a protection device like a freewheeling diode to dissipate the energy stored in the inductor.

### 8.3.5.1 Short-Circuit and Overload Protection

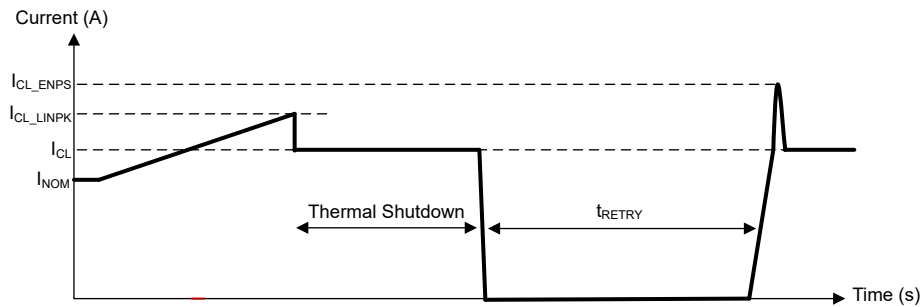

TPS1HTC30-Q1 provides output short-circuit protection to make sure that the device prevents current flow in the event of a low impedance path to GND, removing the risk of damage or significant supply droop. The device is specified to protect against short-circuit events regardless of the state of the ILIM pins and with up to 60V supply at 125°C.

Figure 8-8 shows the behavior of TPS1HTC30-Q1 when a short-circuit occurs and the device is in the on-state and already outputting current. When the internal pass FET is fully enabled, the current clamping settling time is slower so to make sure overshoot is limited, the device implements a fast trip level at a level  $I_{OVCR}$ . When this fast trip threshold is hit, the device immediately shuts off for a short period of time before quickly re-enabling and clamping the current to  $I_{CL}$  level after a brief transient overshoot to the higher peak current ( $I_{CL\_ENPS}$ ) level. The device then keeps the current clamped at the regulation current limit until the thermal shutdown temperature is hit and the device safely shuts off.

**Figure 8-8. On-State Short-Circuit Behavior**

Overload Behavior shows the behavior of the TPS1HTC30-Q1 when there is a small change in impedance that sends the load current above the  $I_{CL}$  threshold. The current rises to  $I_{CL\_LINPK}$  above the regulation level. Then the current limit regulation loop kicks in and the current drops to the  $I_{CL}$  value.

**Figure 8-9. Overload Behavior**

In all of these cases, the internal thermal shutdown is safe to hit repetitively. There is no device risk or lifetime reliability concerns from repeatedly hitting this thermal shutdown level.

### 8.3.5.2 Open-Load Detection

When the main channel is enabled faults are diagnosed by reading the voltage on the SNS pin and judged by the user.

In the off state, if a load is connected, the output voltage is pulled to 0V. In the case of an open load, the output voltage is close to the supply voltage,  $V_S - V_{OUT} < V_{ol,off}$ . The FLT pin goes low to indicate the fault to the MCU, and the SNS pin is pulled up to  $V_{SNSFH}$ . There is always a leakage current  $I_{ol,off}$  present on the output, due to the internal logic control path or external humidity, corrosion, and so forth. Thus, TI implemented an internal pullup resistor to offset the leakage current. This pullup current must be less than the output load current to avoid false detection in the normal operation mode. To reduce the standby current, TI implemented a switch in series with the pullup resistor controlled by the DIAG\_EN pin. The pull up resistor value is  $R_{pu} = 150k\Omega$ .

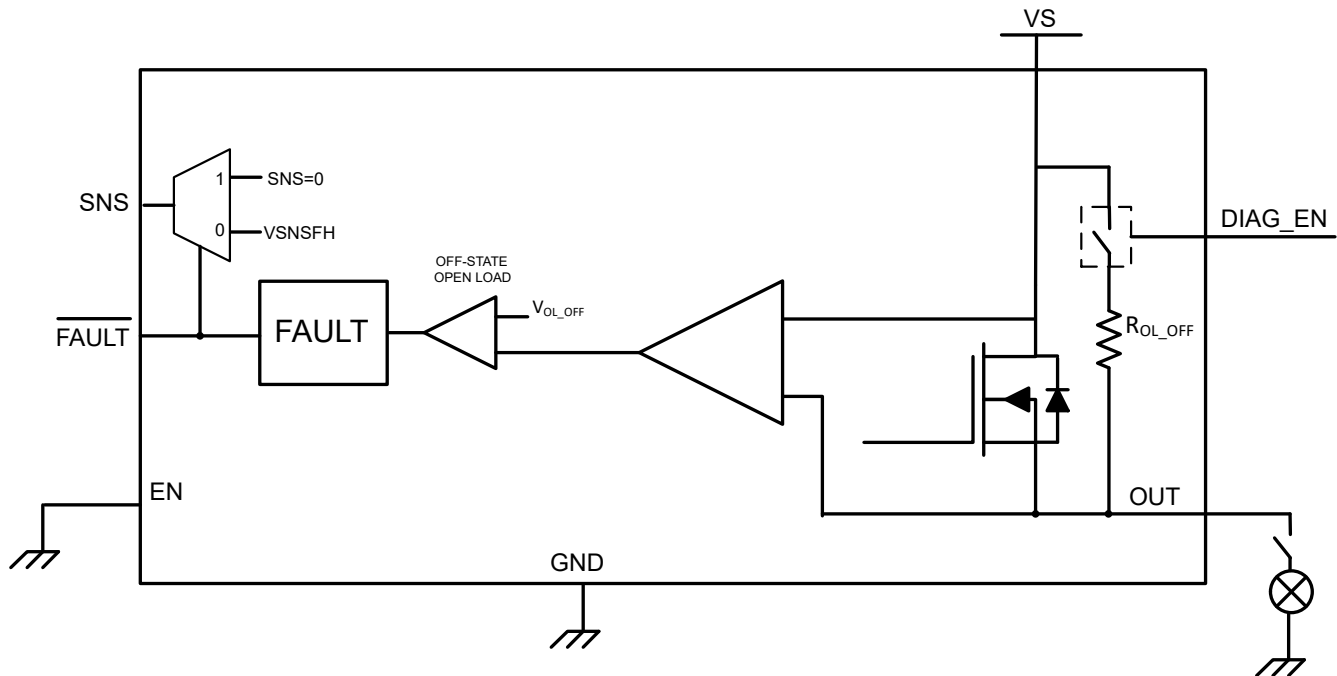

Figure 8-10. Open-Load Detection Circuit

### 8.3.5.3 Thermal Protection Behavior

The thermal protection behavior can be split up into three categories of events that can happen. Figure 8-11 shows each of these categories.

1. **Relative thermal shutdown:** The device is enabled into an overcurrent event. The DIAG\_EN pin is high so that diagnostics can be monitored on SNS and FLT (however, DIAG\_EN being high is not necessary for all protection features to function). The output current rises up to the  $I_{LIM}$  level and the FLT goes low while the SNS goes to  $V_{SNSFH}$ . With this large amount of current going through, the junction temperature of the FET increases rapidly with respect to the controller temperature. When the power FET temperature rises  $T_{REL}$  amount above the controller junction temperature  $\Delta T = T_{FET} - T_{CON} > T_{REL}$ , the device shuts down. The faults are continually shown on SNS and FLT and the part waits for the  $t_{RETRY}$  timer to expire. When  $t_{RETRY}$  timer expires, because the LATCH pin is low and EN is still high, the device comes back on into this  $I_{LIM}$  condition.
2. **Absolute thermal shutdown:** The device is still enabled in an overcurrent event with DIAG\_EN high and LATCH still low. However, in this case the junction temperature rises up and hits an absolute reference temperature,  $T_{ABS}$ , and then shuts down. The device does not recover until both  $T_J < T_{ABS} - T_{hys}$  and the  $t_{RETRY}$  timer has expired.
3. **Latch-off mode:** The device is enabled into an overcurrent event. The DIAG\_EN pin is high so that diagnostics can be monitored on SNS and FLT. The output current rises up to the  $I_{LIM}$  level and the FLT goes low while the SNS goes to  $V_{SNSFH}$ . If the part shuts down due to a thermal fault, either relative thermal shutdown or absolute thermal shutdown, the device does not enable the channel until either the LATCH pin OR the EN pin is toggled.

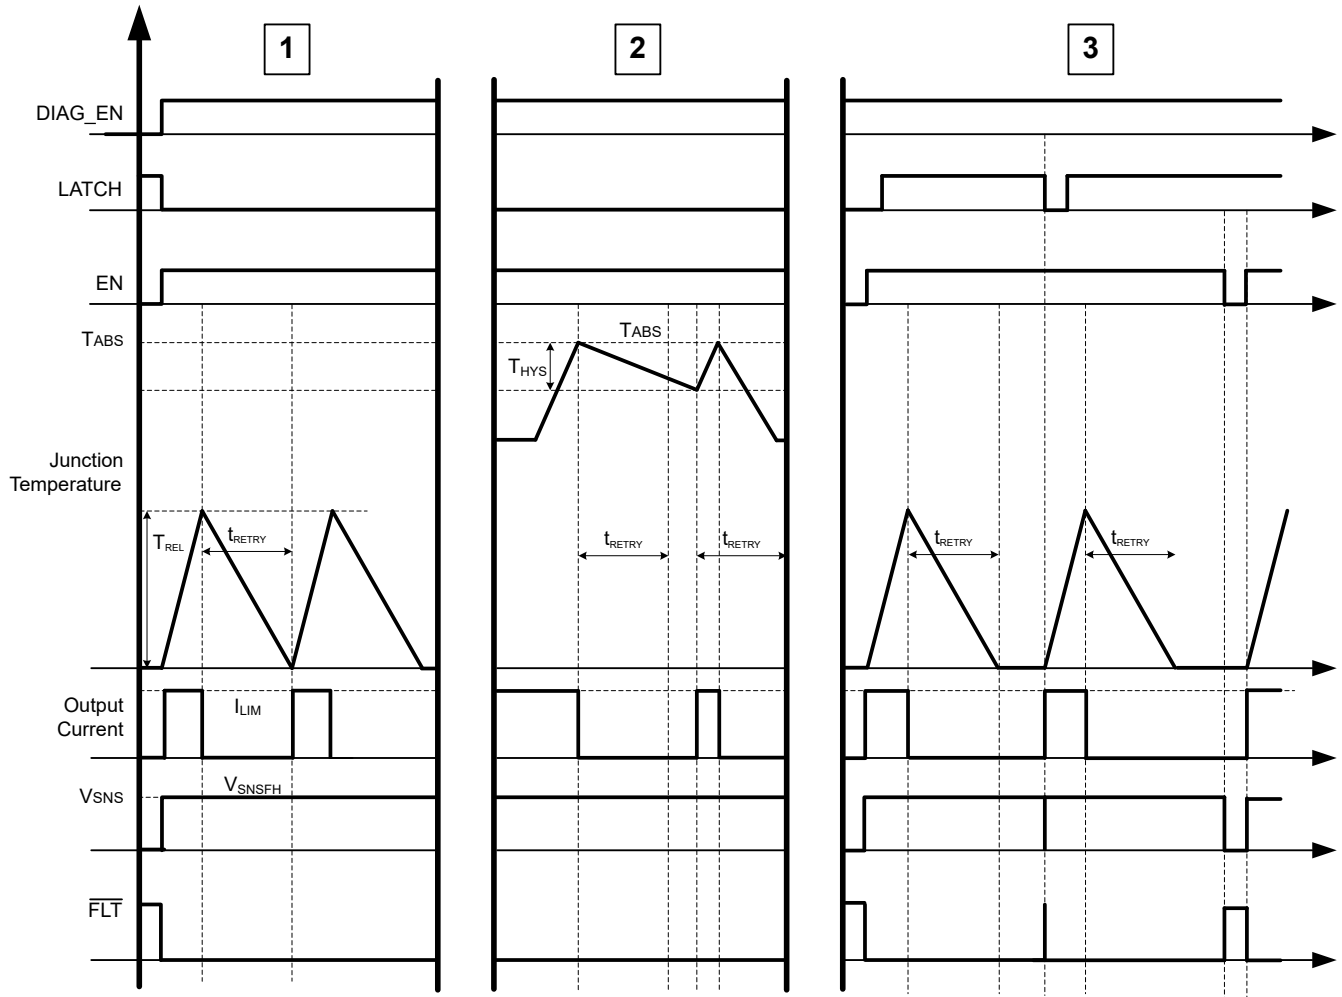

Figure 8-11. Thermal Behavior

#### 8.3.5.4 Overvoltage (OVP) Protection

The TPS1HTC30-Q1 monitors the supply voltage  $V_S$  to prevent unpredictable behaviors in the event that the supply voltage is too high. When the supply increases beyond  $V_{S,OVP\overline{R}}$ , the output stage is shut down automatically. When the supply falls below  $V_{S,OVP\overline{F}}$ , the device turns on. The TPS1HTC30-Q1 integrates a deglitcher to avoid immediate output shutoff from OVP due to short transient events brought about by inductive load oscillations. The TPS1HTC30C-Q1 does not integrate OVP protection and does not turn the device off when higher voltages are present on  $V_S$ .

#### 8.3.5.5 UVLO Protection

The device monitors the supply voltage  $V_S$  to prevent unpredictable behaviors in the event that the supply voltage is too low. When the supply voltage falls down to  $V_{UVLO\overline{F}}$ , the output stage is shut down automatically. When the supply rises up to  $V_{UVLO\overline{R}}$ , the device turns on. If an overcurrent event trips the UVLO threshold, the device shuts off and comes back on into a current limit normally.

### 8.3.5.6 Reverse Polarity Protection

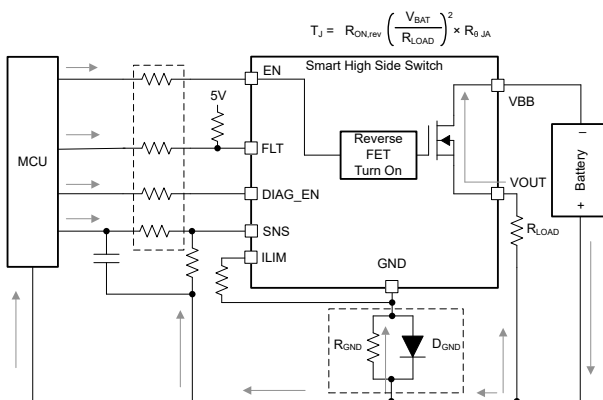

**Method 1:** Blocking diode connected with  $V_S$ . Both the device and load are protected when in reverse polarity. The blocking diode does not allow any of the current to flow during reverse battery condition.

**Figure 8-12. Reverse Protection With Blocking Diode**

**Method 2 (GND network protection):** Only the high-side device is protected under this connection. The load reverse current is limited by the impedance of the load. When reverse polarity happens, the continuous reverse current through the power FET must not make the heat build up be greater than the absolute maximum junction temperature. This can be calculated using the  $R_{ON(REV)}$  value and the  $R_{\theta JA}$  specification. In the reverse battery condition, the FET must turn on to lower the power dissipation. This action is achieved through the path from EN to system ground where the positive voltage is being applied. No matter what types of connection are between the device GND and the board GND, if a GND voltage shift happens, verify that the following proper connections for the normal operation:

- Connect the current limit programmable resistor to the device GND.

**Figure 8-13. Reverse Protection With GND Network**

- **Recommendation – resistor and diode in parallel:** A peak negative spike can occur when the inductive load is switching off, which can damage the HSS or the diode. So, TI recommends a resistor in parallel with the diode when driving an inductive load. The recommended selection are a 1kΩ resistor in parallel with an  $I_F > 100\text{mA}$  diode. If multiple high-side switches are used, the resistor and diode can be shared among devices. In this case, combined  $I_{GND}$  of multiple high-side switches needs to be considered while determining the ground resistor and ground diode.
- **Ground Resistor:** The higher resistor value contributes to a better current limit effect when the reverse battery or negative ISO pulses.

$$R_{GND} \geq \frac{(-V_{CC})}{(-I_{GND})} \quad (9)$$

where

- $-V_{CC}$  is the maximum reverse battery voltage (can come from ISO 7637 pulse 1 and 3a testing).
- $-I_{GND}$  is the maximum reverse current the ground pin can withstand, which is available in [Section 6.1](#).
- **Ground Diode:** A diode is needed to block the reverse voltage, which also brings a ground shift ( $\approx 600\text{mV}$ ). Additionally, the diode must be  $\approx 300\text{V}$  reverse voltage for the ISO 7637 pulse 1 and 3a testing so that the diode does not get biased.

### 8.3.5.7 Protection for MCU I/Os

In many conditions, such as the negative ISO pulse, or the loss of battery with an inductive load, a negative potential on the device GND pin can damage the MCU I/O pins [more likely, the internal circuitry connected to the pins]. Therefore, the serial resistors between MCU and HSS are required.

Also, for proper protection against loss of GND, TI recommends  $5\text{k}\Omega$  resistance for the RPROT resistors.

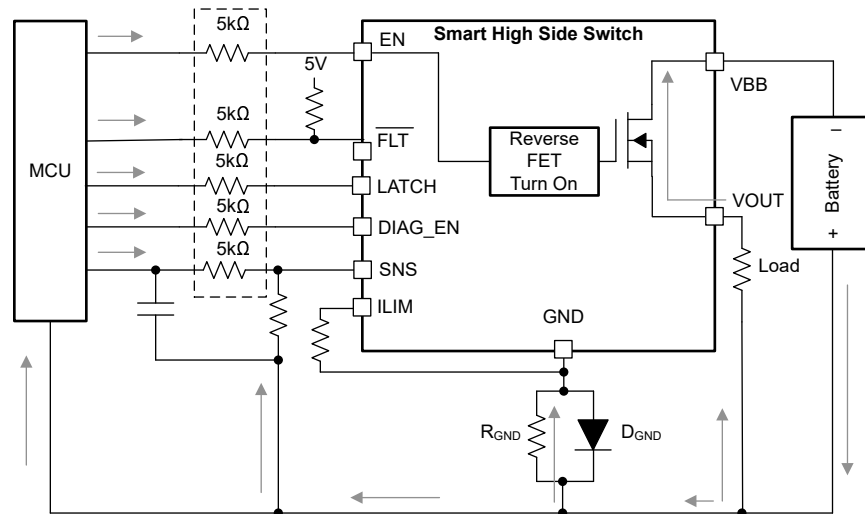

Figure 8-14. MCU IO Protections

### 8.3.6 Diagnostic Enable Function

The diagnostic enable pin, DIAG\_EN, offers multiplexing of the microcontroller diagnostic input for current sense or digital status, by sharing the same sense resistor and ADC line or I/O port among multiple devices.

In addition, during the output-off period, the diagnostic disable function lowers the current consumption for the standby condition. The three working modes in the device are normal mode, standby mode, and standby mode with diagnostic. If off-state power saving is required in the system, the standby current is  $< 500\text{nA}$  with DIAG\_EN low. If the off-state diagnostic is required in the system, the typical standby current is around  $1\text{mA}$  with DIAG\_EN high.

## 8.4 Device Functional Modes

### 8.4.1 Working Mode

The three working modes in the device are normal mode, standby mode, and standby mode with diagnostic. If an off-state power saving is required in the system, the standby current is less than  $500\text{nA}$  with EN and DIAG\_EN low. If an off-state diagnostic is required in the system, the typical standby current is around  $1.2\text{mA}$  with DIAG\_EN high. Note that to enter standby mode requires IN low and  $t > t_{\text{STBY}}$ .  $t_{\text{STBY}}$  is the standby-mode deglitch time, which is used to avoid false triggering or interfere with PWM switching. [Figure 8-15](#) shows a work-mode state-machine state diagram.

**Figure 8-15. Work-Mode State Machine**

## 9.2.2 Detailed Design Procedure

To keep maximum voltage on the SNS pin at an acceptable range for the system, use the following equation to calculate the  $R_{SNS}$ . To achieve better current sense accuracy, a 1% accuracy or better resistor is preferred.

$$(V_{SNSFH} - V_{HR}) \times K_{SNS} \div I_{LOAD,max} \leq V_{ADC,min} \times K_{SNS} \div I_{LOAD,min} \quad (10)$$

**Table 9-1. Typical Application**

Parameter	Value
$V_{DIAG\_EN}$	5V
$I_{LOAD,max}$	5A
$I_{LOAD,min}$	20mA
$V_{ADC,min}$	5mV
$V_{HR}$	1V

For this application, an  $R_{SNS}$  value of approximately 1k $\Omega$  can be selected to satisfy the equation requirements.

$$5mV \times 1300 \div 20mA \leq \cong 1k\Omega \leq (5V - 1V) \times 1300 \div 5A \quad (11)$$

In other applications, more emphasis can be put on the lower end measurable values which increases  $R_{SNS}$ . Likewise, if the higher currents are of more interest the  $R_{SNS}$  can be decreased.

Having the maximum SNS voltage scale with the  $DIAG\_EN$  voltage removes the need for a Zener diode on the SNS pin going to the ADC.

To set the programmable current limit value at 6A, use the following equation to calculate the  $R_{ILIM}$ .

$$R_{ILIM} = \frac{K_{CL}}{I_{LIM}} = \frac{100}{6} = 16.6k\Omega \quad (12)$$

The following factors can affect initial current limiting:

- Application – short to ground or capacitive charging
- High VDS such as 48V
- High load/inrush currents (for example, large capacitors)

Please see the [Short-Circuit and Overload Protection](#) section for a more detailed explanation.

TI recommends  $R_{PROT} = 10k\Omega$  to ensure the current going into the digital pins (EN,  $DIAG\_EN$ , LATCH) is limited.

TI recommends a 1k $\Omega$  resistor and  $\cong 300V$  reverse voltage and  $I_F > 100mA$  diode for the GND network.

### 9.2.2.1 Dynamically Changing Current Limit

The current limit threshold can be changed dynamically by altering the resistance going from the current limit pin to the ground of the device easily. This alteration allows the system to have a different current limit for start-up, when there can be significant inrush current, and during normal operation. The way this is commonly done is by putting two resistors in parallel on the  $ILIM$  pin and having a switch to enable or disable one of the resistors. This set-up can be seen in [Figure 9-2](#). Alternatively, a digital potentiometer can be used to adjust the impedance on the  $ILIM$  pin easily. Take care so that the capacitance on the  $ILIM$  pin is below approximately 100pF to keep the current regulation loop stable. The most common application where this feature is useful is capacitive loads.

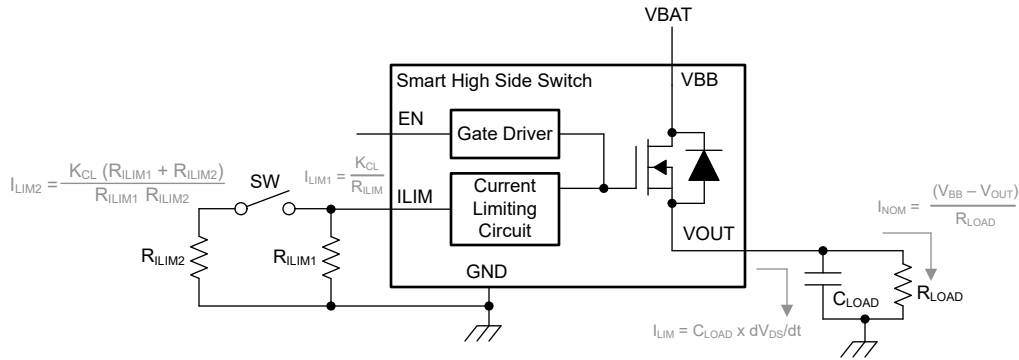

Figure 9-2. Dynamic Changing Current Limit Setup

In a capacitive charging case, the initial current to charge the capacitor is the inrush current. Depending on the system requirements, dynamically changing the current limit can help either charge up a capacitor faster or charge up a larger capacitor. To allow a higher inrush level of current through in the beginning, the switch can be closed making the current limit be according to the equation below.

$$I_{LIM2} = K_{CL} \frac{(R_{ILIM1} + R_{ILIM2})}{(R_{ILIM1} \times R_{ILIM2})} \quad (13)$$

When the inrush event is over and the output voltage is charged up, the switch opens and the current limit is just the  $R_{ILIM1}$  equivalent level. Figure 9-3 shows this timing.

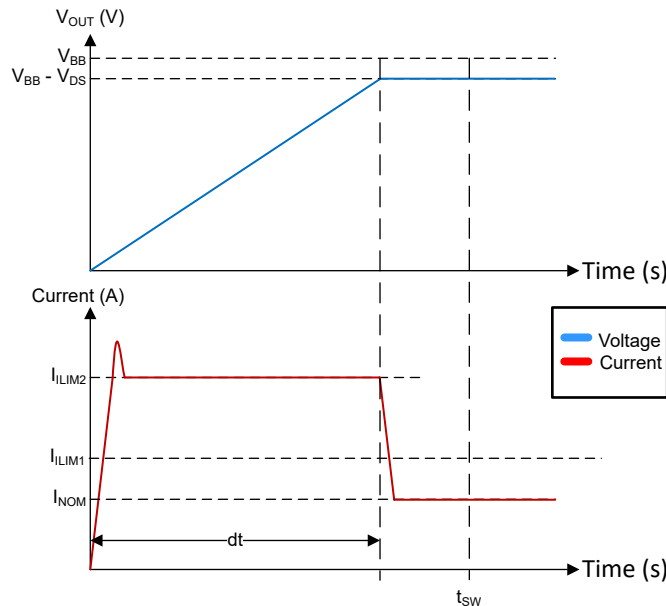

Figure 9-3. Capacitive Charging Changing Current Limit

Alternatively, if the switch is open, the current limit starts out at a lower value and then the switch can be closed when the capacitance gets charged up. This lower current limit level allows higher value capacitance to be charged up. The timing diagram can be seen in Figure 9-4.

**Figure 9-4. Large Capacitive Charging Changing Current Limit**

**9.2.3 Application Curves**

Figure 9-5 shows a test example of a discharging a 400mH inductor. Test conditions:  $V_S = 24V$ , input is high to low, load is 400mH.

## 9.3 Power Supply Recommendations

The device is qualified for both automotive and industrial applications. The normal power supply connection is a 24V automotive system. The supply voltage must be within the range specified in the [Recommended Operating Conditions](#).

**Table 9-2. Voltage Operating Ranges**

VS Voltage Range	Note
6V to 10V	Extended lower 24V automotive battery operation such as cold crank and start-stop. Device is fully functional and protected but some parametrics such as $R_{ON}$ , current sense accuracy, current limit accuracy and timing parameters can deviate from specifications. Check the individual specifications in the Electrical Characteristics to confirm the voltage range it is applicable for.
10V to 32V	Nominal 24V automotive battery voltage range. All parametric specifications apply and the device is fully functional and protected.
32V to 60V	Extended upper 24V automotive battery operation such as double battery. Device is fully functional and protected but some parametrics such as timing parameters can deviate from specifications. Check the individual specifications in the Electrical Characteristics to confirm the voltage range it is applicable for.
60V	24V battery load dump voltage. Device is operational and lets the pulse pass through without being damaged and is fully protect against short circuits.
70V	Maximum DC rating for the TPS1HTC30C-Q1. Device is operational and lets the pulse pass through without being damaged.

## 9.4 Layout

### 9.4.1 Layout Guidelines

To prevent thermal shutdown,  $T_J$  must be less than 150°C. If the output current is very high, the power dissipation can be large. The HTSSOP package has good thermal impedance. However, the PCB layout is very important. Good PCB design can optimize heat transfer, which is absolutely essential for the long-term reliability of the device.

- Maximize the copper coverage on the PCB to increase the thermal conductivity of the board. The major heat-flow path from the package to the ambient is through the copper on the PCB. Maximum copper is extremely important when there are not any heat sinks attached to the PCB on the other side of the board opposite the package.
- Add as many thermal vias as possible directly under the package ground pad to optimize the thermal conductivity of the board.
- Make sure all thermal vias are either be plated shut or plugged and capped on both sides of the board to prevent solder voids. To make sure of reliability and performance, the solder coverage must be at least 85%.

### 9.4.2 Layout Example

#### 9.4.2.1 Without a GND Network

Without a GND network, tie the thermal pad directly to the board GND copper for better thermal performance.

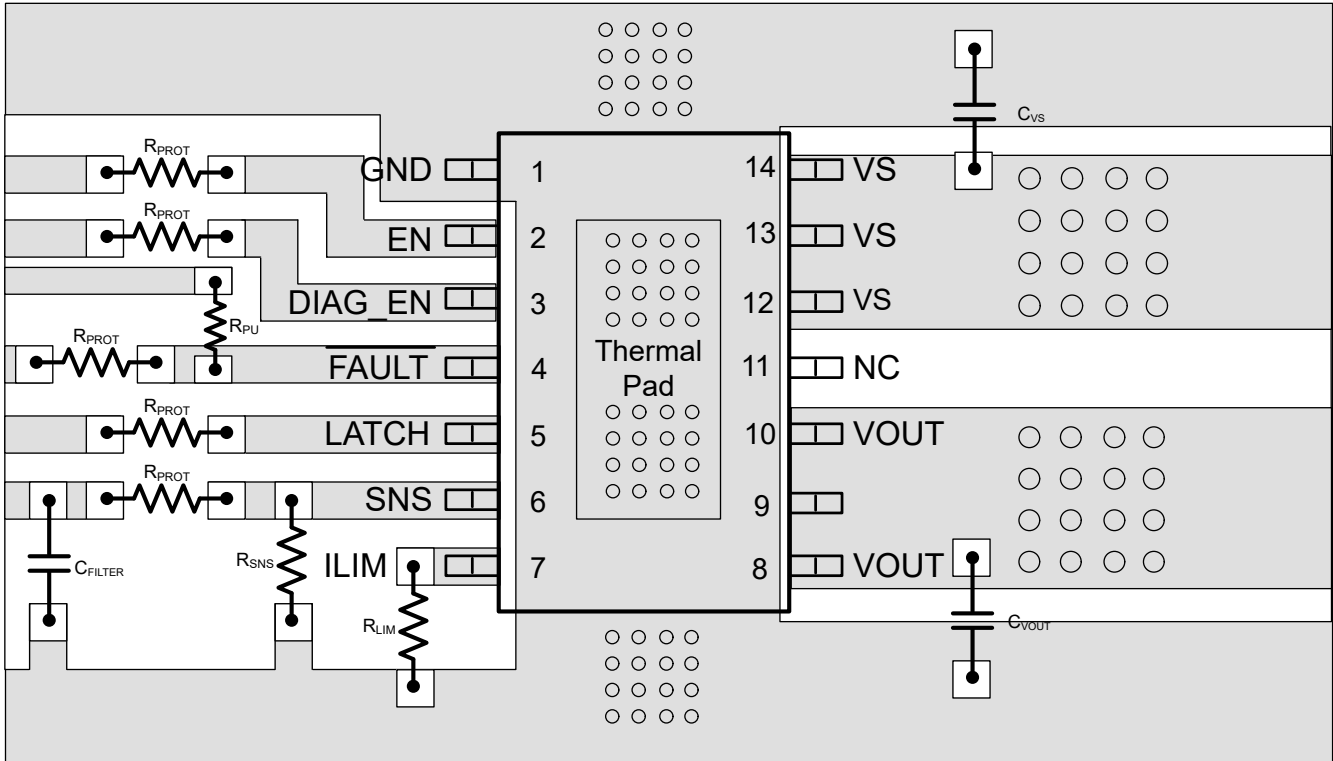

Figure 9-6. Layout Without a GND Network

9.4.2.2 With a GND Network

With a GND network, tie the thermal pad with a single trace through the GND network to the board GND copper.

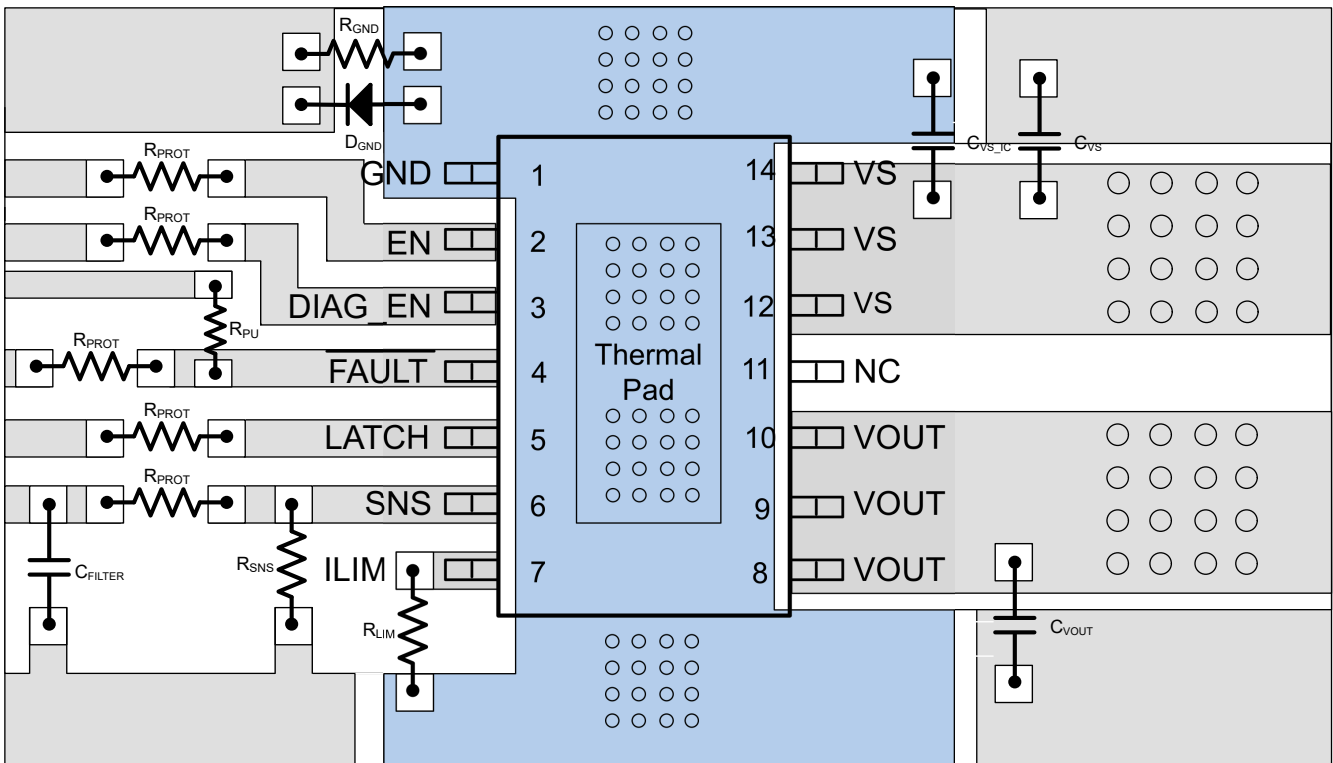

Figure 9-7. Layout With a GND Network

### 9.4.2.3 Thermal Considerations

This device possesses thermal shutdown (TABS) circuitry as a protection from overheating. For continuous normal operation, the junction temperature must not exceed the thermal-shutdown trip point. If the junction temperature exceeds the thermal-shutdown trip point, the output turns off. When the junction temperature falls below the thermal-shutdown trip point, the output turns on again.

Calculate the power dissipated by the device according to [Equation 14](#).

$$P_T = I_{OUT}^2 \times R_{DS(on)} + V_S \times I_{NOM} \quad (14)$$

where

- $P_T$  = Total power dissipation of the device

After determining the power dissipated by the device, calculate the junction temperature from the ambient temperature and the device thermal impedance.

$$T_J = T_A + R_{\theta JA} \times P_T \quad (15)$$

### 10.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

(1) **Status:** For more details on status, see our [product life cycle](#).

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "-" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
